# The Biblatex Package

## **Programmable Bibliographies and Citations**

Philipp Lehman Version 3.0 (with Philip Kime, Audrey Boruvka 20/04/2015 and Joseph Wright)

## Biblatex 宏包说明文档摘译

胡振震1

2016-02-08

译者按: 之所以摘译 biblatex, 一是出于对 keep texing 的兴趣, 二是考虑到中文资料里总体介绍 latex 的资料其实较多,反而是在一些专项部分中文资料较少,看宏包英文说明当然没有问题,但有的文档内容长达几百页, 一般用户真心没有精力去看, 即便是找一些自己需要的功能也比较麻烦, 所以考虑对参考文献的 biblatex 宏包文档进行摘译, 是希望能在这一方面有所贡献。应该说, biblatex 宏包的很多功能比如文献表划分, 文献集, 样式定制, 动态数据处理等, 在科技论文或书籍写作特别是对参考文献著录和标注有特殊要求的情况下是很有用的。

总之,本文总体任务是完成 biblatex 宏包说明文档关键内容的摘译,希望能对有深度定制参考文献要求的用户有所帮助,当然也希望能使中文 latex 资料库更为全面和深入。需要说明的是,限于作者水平,其中难免存在一些错误和理解不到位的地方,欢迎批评指正,欢迎@译者邮箱。最后感谢 CTEX 和 Latexstudio 论坛,感谢论坛上各位作者关于 biblatex 参考文献方面的工作分享和经验介绍。

## 1 引言

这是关于 biblatex 包的语法文档,使用范例文档参考文档 $^2$ 。快速开始,请浏览 §§ 1.1, 2.1, 2.2, 2.3, 3.1, 3.3, 3.6, 3.7, 3.11 节。

译文文档说明:译文文档直接在原 biblatex 说明文档基础上进行修改, biblatex 说明文档除了使用了一些基本宏包外主要使用类和包文件包括: scrartcl.cls, ltx-dockit.cls, ltxdockit.cfg, ltxdockit.def, btxdockit.sty, ltxdockit.sty。需要修改一些默认设置和命令可在这些文件中查找。

## 1.1 关于 biblatex

biblatex 包提供了一套与 latex 配合使用的高级参考文献工具。该包是 latex 提供的参考文献功能的完整再实现。该包默认使用自定义后端 biber,用于处理 bibtex 格式文件、执行排序和生成标签 (以及其它更多工作)。参考文献的格式化完全由 tex 宏包控制。只要具备一定的 latex 知识就足以设计新的参考文献著录样式和标注样式。

biblatex 也支持参考文献表细分,支持在一个文档内包含多个参考文献表,支持生成参考文献局部信息表比如多个不同域的缩略词。参考文献表可以根据主题进行分块或者分段。与参考文献著录样式类似,所有的标注(引用)命令也可以自由定义。

提供的功能还包括: 文献数据的 Unicode 支持、自定义排序、不同排序方式的多参考文献表、自定义标签和动态数据修改。 biber/biblatex 的版本兼容性见§1.5.5节。该包可完全实现本地化,可与 babel 或 polyglossia 包配合使用,该包支持的语言详见表 table 2。

## 1.2 许可

Copyright © 2006–2012 Philipp Lehman, 2012–2013 Philip Kime, Audrey Boruvka, Joseph Wright. Permission is granted to copy, distribute and/or modify this software under the terms of the LaTeX Project Public License, version  $1.3.^3$ 

<sup>&</sup>lt;sup>2</sup>http://www.ctan.org/tex-archive/macros/latex/contrib/biblatex/doc/examples

<sup>3</sup>http://www.ctan.org/tex-archive/macros/latex/base/lppl.txt

## 1.3 反馈

请使用 github 的 biblatex 项目页报告 bug 和提交所需功能<sup>4</sup>。若寻求帮助请在 comp.text.tex 新闻组或 tex-latex 讨论区提交问题<sup>5</sup>。

## 1.4 致谢

The language modules of this package are made possible thanks to the following contributors: Augusto Ritter Stoffel, Mateus Araújo (Brazilian); Sebastià Vila-Marta (Catalan); Ivo Pletikosić (Croatian); Michal Hoftich (Czech); Jonas Nyrup (Danish); Johannes Wilm (Danish/Norwegian); Alexander van Loon, Pieter Belmans, Hendrik Maryns (Dutch); Hannu Väisänen, Janne Kujanpää (Finnish); Denis Bitouzé (French); Apostolos Syropoulos, Prokopis (Greek); Baldur Kristinsson (Icelandic); Enrico Gregorio, Andrea Marchitelli (Italian); Håkon Malmedal (Norwegian); Anastasia Kandulina, Yuriy Chernyshov (Polish); José Carlos Santos (Portuguese); Oleg Domanov (Russian); Tea Tušar and Bogdan Filipič (Slovene); Ignacio Fernández Galván (Spanish); Per Starbäck, Carl-Gustav Werner, Filip Åsblom (Swedish).

## 1.5 前提与必备

本节介绍所需资源和兼容性问题。

#### 1.5.1 必须资源

如下资源是必须的,否则 biblatex 无法正常工作

e-TeX Biblatex 宏包需要e-TeX。

Biber Biber 是 Biblatex 的默认后端,只需要一个后端 BibTeX 或者 Biber。

BibTeX Biblatex 可以使用传统的的 BibTeX 作为数据后端。

etoolbox 自动加载,提供 Biblatex 所需的通用编程工具。

kvoptions 自动加载,用于内部选项处理。

logreg 自动加载,提供了向辅助日志文件写入机器可读信息的前端。

除了上述资源,Biblatex 还需要标准 LaTeX 宏包keyval 、ifthen和url 。这些包包含在所有通用 TeX 发行版中,也自动进行加载。

## 1.5.2 推荐包

The packages listed in this section are not required for Biblatex to function, but they provide recommended additional functions or enhance existing features. The package loading order does not matter.

<sup>4</sup>http://github.com/plk/biblatex

<sup>5</sup>http://tex.stackexchange.com/questions/tagged/biblatex

babel/polyglossia The babel and polyglossia packages provides the core architecture for multilingual typesetting. If you are writing in a language other than American English, using one of these packages is strongly recommended. If loaded, Biblatex package will detect babel or polyglossia automatically.

csquotes If this package is available, Biblatex will use its language sensitive quotation facilities to enclose certain titles in quotation marks. If not, Biblatex uses quotes suitable for American English as a fallback. When writing in any other language, loading csquotes is strongly recommended.<sup>6</sup>

xpatch The xpatch package extends the patching commands of etoolbox to Biblatex bibliography macros, drivers and formatting directives.<sup>7</sup>

#### 1.5.3 兼容的包

The Biblatex package provides dedicated compatibility code for the classes and packages listed in this section.

hyperref The hyperref package transforms citations into hyperlinks. See the hyperref and backref package options in § 3.1.2.1 for further details. When using the hyperref package, it is preferable to load it after Biblatex.

showkeys The showkeys package prints the internal keys of, among other things, citations in the text and items in the bibliography. The package loading order does not matter.

memoir When using the memoir class, the default bibliography headings are adapted such that they blend well with the default layout of this class. See § 3.12.2 for further usage hints.

KOMA-Script When using any of the scrartcl, scrbook, or scrreprt classes, the default bibliography headings are adapted such that they blend with the default layout of these classes. See § 3.12.1 for further usage hints.

## 1.5.4 不兼容的包

The packages listed in this section are not compatible with Biblatex. Since it reimplements the bibliographic facilities of LaTeX from the ground up, Biblatex naturally conflicts with all packages modifying the same facilities. This is not specific to Biblatex. Some of the packages listed below are also incompatible with each other for the same reason.

babelbib The babelbib package provides support for multilingual bibliographies. This is a standard feature of Biblatex. Use the langid field and the package option autolang for similar functionality. Note that Biblatex automatically adjusts to the main document language if babel or polyglossia is loaded. You only need the above mentioned features if you want to switch languages on a per-entry basis within the bibliography. See §§ 2.2.3 and 3.1.2.1 for details. Also see § 3.8.

<sup>6</sup>http://www.ctan.org/tex-archive/macros/latex/contrib/csquotes/

Thttp://www.ctan.org/tex-archive/macros/latex/contrib/xpatch/

- backref The backref package creates back references in the bibliography. See the package options hyperref and backref in § 3.1.2.1 for comparable functionality.
- The bibtopic package provides support for bibliographies subdivided by topic, type, or other criteria. For bibliographies subdivided by topic, see the category feature in § 3.6.7 and the corresponding filters in § 3.6.2. Alternatively, you may use the keywords field in conjunction with the keyword and notkeyword filters for comparable functionality, see §§ 2.2.3 and 3.6.2 for details. For bibliographies subdivided by type, use the type and nottype filters. Also see § 3.11.4 for examples.
- bibunits The bibunits package provides support for multiple partial (e.g., per chapter) bibliographies. See chapterbib.
- chapterbib The chapterbib package provides support for multiple partial bibliographies. Use the refsection environment and the section filter for comparable functionality. Alternatively, you might also want to use the refsegment environment and the segment filter. See §§ 3.6.5, 3.6.6, 3.6.2 for details. Also see § 3.11.3 for examples.
  - cite The cite package automatically sorts numeric citations and can compress a list of consecutive numbers to a range. It also makes the punctuation used in citations configurable. For sorted and compressed numeric citations, see the sortcites package option in § 3.1.2.1 and the numeric-comp citation style in § 3.3.1. For configurable punctuation, see § 3.9.
  - citeref Another package for creating back references in the bibliography. See backref.
  - inlinebib The inlinebib package is designed for traditional citations given in footnotes. For comparable functionality, see the verbose citation styles in § 3.3.1.
  - jurabib Originally designed for citations in law studies and (mostly German) judicial documents, the jurabib package also provides features aimed at users in the humanities. In terms of the features provided, there are some similarities between jurabib and Biblatex but the approaches taken by both packages are quite different. Since both jurabib and Biblatex are full-featured packages, the list of similarities and differences is too long to be discussed here.
    - The moite package provides support for grouped citations, i. e., multiple items can be cited as a single reference and listed as a single block in the bibliography. The citation groups are defined as the items are cited. This only works with unsorted bibliographies. The Biblatex package also supports grouped citations, which are called 'entry sets' or 'reference sets' in this manual. See §§ 3.11.5, 3.6.12, 3.7.10 for details.
- mciteplus A significantly enhanced reimplementation of the mcite package which supports grouping in sorted bibliographies. See mcite.
- multibib The multibib package provides support for bibliographies subdivided by topic or other criteria. See bibtopic.

1.9 1.8	2.9 2.8
1.8	2.8
	2.0
1.7	2.7
1.6	2.6

0.9.2	1.4x
0.9.1	1.4x
0.9	1.4x

Table 1: Biber/Biblatex compatibility matrix

natbib The natbib package supports numeric and author-year citation schemes, incorporating sorting and compression code found in the cite package. It also provides additional citation commands and several configuration options. See the numeric and author-year citation styles and their variants in § 3.3.1, the sortcites package option in § 3.1.2.1, the citation commands in § 3.7, and the facilities discussed in §§ 3.6.8, 3.6.9, 3.9 for comparable functionality. Also see § 3.7.9.

splitbib The splitbib package provides support for bibliographies subdivided by topic. See bibtopic.

titlesec The titlesec package redefines user-level document division commands such as \chapter or \section. This approach is not compatible with internal command changes applied by the Biblatex refsection and refsegment option settings described in § 3.1.2.1.

ucs The ucs package provides support for UTF-8 encoded input. Either use inputenc's standard utf8 module or a Unicode enabled engine such as XeTeX or LuaTeX instead.

## 1.5.5 biber/biblatex 兼容性

Biber versions are closely coupled with Biblatex versions. You need to have the right combination of the two. Biber will warn you during processing if it encounters information which comes from a Biblatex version which is incompatible. table 1 shows a compatibility matrix for the recent versions.

## 2 数据库指南

有必要区分一下 bibtex 程序和 bibtex 文件格式。biblatex 无论有无 bibtex 程序都可以使用,因为其默认使用的后端 biber 完全支持 bibtex 文件格式(bib)。当使用 biber 后端时,用户仅需少量修改就可以使用 bibtex 数据文件。注意当使用 bibtex 后端时,无法使用任意的 bst 文件,因为该包基于一个特定的 bibtex 接口。当使用 bibtex 时,biblatex 只能使用自己的样式文件 (即通过 biblatex 宏包所定义的参考文献样式)。除非特殊说明,下面的条目指南适用于所有的后端。

本节描述在 blx-dm.def 中定义的默认数据模型。blx-dm.def 文件是宏包的一部分。数据模型的定义由§4.5.3节中的宏实现。可以重新定义 Biblatex 和 Biber 所用的数据模型。因此数据源可以包括所有的条目类型和域(当然这需要样式文件支持)。数据模型规范允许定义约束,因此数据源可以根据数据模型进行校验(使用 Biber 的 --validate\_datamodel 选项)。若需要定制数据模型,请参考§4.5.3节。

## 2.1 条目类型

本节介绍默认数据类型支持的条目类型及每种条目类型支持的域。

## 2.1.1 常规类型

下面的列表说明了每种条目类型支持的域。注意,每种条目类型的预的使用是由参考文献样式决定的。下面的列表有两个目的,一是,说明有本包提供的标准样式支持的域,二是,作为定制样式的模板。注意,所谓需要的域并不是严格的必不可少,详见§2.3.2。而标记"可选"的域技术上是可选的。而参考文献样式规则常需要多于需要的域。默认的数据类型,定义了一些数据域的约束。比如 ISBNs和一些特殊的域如gender。但约束的校验只有在 biber 带校验选项时进行。通用域如abstract,annotation,label 和 shorthand 并不在下面列表中,因为他们独立于条目类型,§2.2.3节讨论的特殊域,同样,独立于条目类型,不在下面的列表中,默认的支持类型规范,见文件blx-dm.def,内有 Biblatex 的完整规范。

article 指期刊,杂志,报纸,或其他周期性刊物的文章。刊物名在journaltitle 域中,If the issue has its own title in addition to the main title of the periodical, it goes in the issuetitle field. 注意:刊物的editor及相关域,指的是期刊的,而translator及其相关域指的是文章的。

需要域: author, title, journaltitle, year/date。

可选域: translator, annotator, commentator, subtitle, titleaddon, editor, editora, editorb, editorc, journalsubtitle, issuesubtitle, language, origlanguage, series, volume, number, eid, issue, month, pages, version, note, issn, addendum, pubstate, doi, eprint, eprintclass, eprinttype, url, urldate。

book 单卷书有一个或多个作者。这些这些作者作为整体共享该工作,该条目涵盖了传统 bibtex 中的@inbook 类型,详见 § 2.3.1。需要域: author, title, year/date 可选

域: editor, editora, editorb, editorc, translator, annotator, commentator, introduction, foreword, afterword, subtitle, titleaddon, maintitle, mainsubtitle, maintitleaddon, language, origlanguage, volume, part, edition, volumes, series, number, note, publisher, location, isbn, chapter, pages, pagetotal, addendum, pubstate, doi, eprint, eprintclass, eprinttype, url, urldate

mvbook 多卷书,为了向后兼容,多卷书也可用@book类,然而建议最好使用专用类@mvbook。

需要域: author, title, year/date。可选域: editor, editora, editorb, editorc, translator, annotator, commentator, introduction, foreword, afterword, subtitle, titleaddon, language, origlanguage, edition, volumes, series, number, note, publisher, location, isbn, pagetotal, addendum, pubstate, doi, eprint, eprintclass, eprinttype, url, urldate。

inbook 书的一部分,具有自有单元和标题,注意:该类的定义不同于标准 BibTeX 给出的 定义,见 § 2.3.1。

Required fields: author, title, booktitle, year/date

Optional fields: bookauthor, editor, editora, editorb, editorc, translator, annotator, commentator, introduction, foreword, afterword, subtitle, titleaddon, maintitle, mainsubtitle, maintitleaddon, booksubtitle, booktitleaddon, language, origlanguage, volume, part, edition, volumes, series, number, note, publisher, location, isbn, chapter, pages, addendum, pubstate, doi, eprint, eprintclass, eprinttype, url, urldate

bookinbook 类似于@inbook,但用于原本以单本书出版的工作,典型例子是:搜集一个作者的多个工作进行重印。

suppbook @book (书)的补充材料,与@inbook类密切相关,不同于@inbook 类是书的一部分,具有自己的标题,(比如,相同作者论文集中的一篇论文),这个类型常用于书的元素如:序,简介,前言,后记等,常有通用名。有时需要定制样式区别于@inbook。标准样式则认为它是@inbook的别名。

booklet 类似于书,但没有正式出版机构,若适当的话,使用howpublished域,可以自由格式提供出版信息。type域有时也很有用。

Required fields: author/editor, title, year/date

Optional fields: subtitle, titleaddon, language, howpublished, type, note, location, chapter, pages, pagetotal, addendum, pubstate, doi, eprint, eprintclass, eprinttype, url, urldate

collection 单卷文集由多个具有不同标题和作者的独立工作构成,作为一个整体没有全局作者,常有一个编者。

Required fields: editor, title, year/date

Optional fields: editora, editorb, editorc, translator, annotator, commentator, introduction, foreword, afterword, subtitle, titleaddon, maintitle, mainsubtitle, maintitleaddon, language, origlanguage, volume, part, edition, volumes, series, number, note, publisher, location, isbn, chapter, pages, pagetotal, addendum, pubstate, doi, eprint, eprintclass, eprinttype, url, urldate

mycollection

多卷文集,类似于 mvbook 之于 book

Required fields: editor, title, year/date

Optional fields: editora, editorb, editorc, translator, annotator, commentator, introduction, foreword, afterword, subtitle, titleaddon, language, origlanguage, edition, volumes, series, number, note, publisher, location, isbn, pagetotal, addendum, pubstate, doi, eprint, eprintclass, eprinttype, url, urldate

incollection

类似于 inbook 之于 book, author 指的是 title的作者。editor 指的是 booktitle (即文集的标题)的编者。

Required fields: author, title, booktitle, year/date

Optional fields: editor, editora, editorb, editorc, translator, annotator, commentator, introduction, foreword, afterword, subtitle, titleaddon, maintitle, mainsubtitle, maintitleaddon, booksubtitle, booktitleaddon, language, origlanguage, volume, part, edition, volumes, series, number, note, publisher, location, isbn, chapter, pages, addendum, pubstate, doi, eprint, eprintclass, eprinttype, url, urldate

suppcollection

类似于 suppbook 之于 book。标准样式将其认为是@incollection的别名。

manual 技术或其它文档,不必然是出版的形式,作者域author或编者域 editor可忽略见 § 2.3.2。

Required fields: author/editor, title, year/date

Optional fields: subtitle, titleaddon, language, edition, type, series, number, version, note, organization, publisher, location, isbn, chapter, pages, pagetotal, addendum, pubstate, doi, eprint, eprintclass, eprinttype, url, urldate

misc 备选类型,当条目无法分类为其他条目时,可使用。适当的话,使用howpublished域,可以自由格式提供出版信息。type域有时也很有用。author,editor,和year可忽略对于§2.3.2节。

Required fields: author/editor, title, year/date

Optional fields: subtitle, titleaddon, language, howpublished, type, version, note, organization, location, date, month, year, addendum, pubstate, doi, eprint, eprintclass, eprinttype, url, urldate

online 在线资源, author (作者), editor (编者), 和year (编者) 可忽略对于 § 2.3.2 节。 该类用于网址等本身就是的在线资源,注意: 所有类型都支持url域,比如: 当增加一篇来自在线期刊的文章,应优先使用@article类和它的url域。

Required fields: author/editor, title, year/date, url

Optional fields: subtitle, titleaddon, language, version, note, organization, date, month, year, addendum, pubstate, urldate

patent 专利或专利申请。号码或记录号在number域中给出,type用于描述类型,location用于描述专利范围,如果存在暗指的范围不同的情况。注意,location 以 key list 的方式处理,详见 § 2.2.1节。

Required fields: author, title, number, year/date

Optional fields: holder, subtitle, titleaddon, type, version, location, note, date, month, year, addendum, pubstate, doi, eprint, eprintclass, eprinttype, url, urldate

periodical 周期性刊物的某一完整出版物,比如某一期刊的特刊,标题在title 域中给出。如果该出版物有其自由标题,除了在期刊的主标题外,放在issuetitle域中。editor域可忽略,对于 § 2.3.2节。

Required fields: editor, title, year/date

Optional fields: editora, editorb, editorc, subtitle, issuetitle, issuesubtitle, language, series, volume, number, issue, date, month, year, note, issn, addendum, pubstate, doi, eprint, eprintclass, eprinttype, url, urldate

suppperiodical 类似于 suppbook 之于 book,在标准样式中与@article 类相同处理,(可以认为@article类型就是@inperiodical类)。该类型应用于诸如:常规栏目,卜告,或者给编者的信等具有通用名的资料很有用。

proceedings 单卷会议进展成果,该类与@collection类似,支持可选的organization域 用于给出主办机构,editor域可忽略对于 § 2.3.2节。

Required fields: title, year/date

Optional fields: editor, subtitle, titleaddon, maintitle, mainsubtitle, maintitleaddon, eventtitle, eventtitleaddon, eventdate, venue, language, volume, part, volumes, series, number, note, organization, publisher, location, month, isbn, chapter, pages, pagetotal, addendum, pubstate, doi, eprint, eprintclass, eprinttype, url, urldate

mvproceedings 多卷@proceedings条目,类似于 mvbook 之于 book。

Required fields: title, year/date

Optional fields: editor, subtitle, titleaddon, eventtitle, eventtitleaddon, eventdate, venue, language, volumes, series, number, note, organization, publisher, location, month, isbn, pagetotal, addendum, pubstate, doi, eprint, eprintclass, eprinttype, url, urldate

inproceedings 会议进展中的一篇文章,类似于 inbook 之于 book,支持可选organization域。

Required fields: author, title, booktitle, year/date

Optional fields: editor, subtitle, titleaddon, maintitle, mainsubtitle, maintitleaddon, booksubtitle, booktitleaddon, eventtitle, eventtitleaddon, eventdate, venue, language, volume, part, volumes, series, number, note, organization, publisher, location, month, isbn, chapter, pages, addendum, pubstate, doi, eprint, eprintclass, eprinttype, url, urldate

reference 单卷参考文献集,诸如百科全书或词典,它是通用@collection类的特殊变种,标准样式中与@collection相同处理。

mvreference 多卷文集献,标准样式中是@mvcollection的别名,类似于 mvbook 之于 book。

inreference 参考文献集中的一篇文章,类似于@incollection类条目,标准样式中与@incollection相同处理。

report 技术报告,研究报告或大学和一些机构的白皮书。用type域明确报告的类型,主办机构institution域中。

Required fields: author, title, type, institution, year/date

Optional fields: subtitle, titleaddon, language, number, version, note, location, month, isrn, chapter, pages, pagetotal, addendum, pubstate, doi, eprint, eprintclass, eprinttype, url, urldate

set 条目集,是一种特殊类型条目,详见 see § 3.11.5节。

thesis 学位论文用于在教育机构中满足学位要求,用type域规定论文的类型。

Required fields: author, title, type, institution, year/date

Optional fields: subtitle, titleaddon, language, note, location, month, isbn, chapter, pages, pagetotal, addendum, pubstate, doi, eprint, eprintclass, eprinttype, url, urldate

unpublished 没有正式发表的有作者和标题的工作,如手稿,讲话稿等。需要的话,可使用howpublished域和note域,以自由格式提供附加信息。

Required fields: author, title, year/date

Optional fields: subtitle, titleaddon, language, howpublished, note, location, isbn, date, month, year, addendum, pubstate, url, urldate

xdata 特殊类型,@xdata 条目记录可能继承自使用xdata域的其他条目的数据,这一 Biber only 类型只是作为数据容器,不可被引用或加入到参考文献中,详见 § 3.11.6节。

custom[a-f] 用于特殊参考文献样式的自定义类型,标准样式中不使用。

## 2.1.2 类型别名

本节中列出的类型用于向下兼容传统的类型。这些别名由后端在数据处理时一并处理,样式中仅能见到这些别名所指代的类型,而一种未知的类型一般输出为@misc条目。

conference BibTeX 遗留的@inproceedings的别名。

electronic @online的别名。

mastersthesis 类似于@thesis除了type域是可选的,默认为'Master's thesis'。可使用type域 重定义。

phdthesis 类似于@thesis除了type域是可选的,默认为'PhD thesis'。可使用type域重定义。

techreport 类似于@report除了type域是可选的,默认为'technical report'。可使用type域 重定义。

www @online的别名,用于兼容jurabib。

## 2.1.3 不支持的条目类型

本节中的条目类型类似于自定义类型,标准样式不支持这些类型,若使用标准样式,他们将会以@misc条目类处理。

artwork 可视艺术作品,如绘画,雕像,装饰。

audio 声音记录,典型如:有声 CD, dvd,有声磁带或类似媒介,也可参考@music。

bibnote 该类条目不象其它类型用于bib文件中,它用于第三方宏包比如notes2bib。注 嬴放在note域中。要注意:@bibnote类型与命令\defbibnote没有任何关系。\defbibnote命令用于在参考文献开头或结尾添加评注,而@bibnote 作为条目应用于提供尾注的宏包。

commentary 评注(集注),与普通书籍的差异在于它具有法律效力,如法律评注。

image 照片,图片类媒介。

jurisdiction 法院记录,如判决和类似文书。

legislation 法律,提案,立法建议或类似东西。

legal 如条约等法律文书。

letter 个人通信,如信,电邮,备忘等。

movie 电影。也可参见@video。

music 音乐记录, @audio的一种具体形式。

performance 音乐或戏剧表演和其它一些表演艺术工作。这一条目类型指的是表演的事件,而不是记录,打分或剧本。

review 工作回顾,是@article的更具体形式。标准样式中以@article处理。

software 电脑软件。

standard 国内和国际标准,由国内和国际的标准组织(如国际标准组织)发布。

video 音视频,典型如: dvd, VHS 等媒介,可参见@movie。

## 2.2 条目域 Entry Fields

本节给出了 biblatex 默认数据模型支持域的概览,数据模型使用的数据类的介绍 参考 § 2.2.1小节,实际的域的列表见 §§ 2.2.2 and 2.2.3小节。

## 2.2.1 数据类型 Data Types

在数据源文件如一个bib文件中,所有的参考文献数据都是以域的形式给出的。其中一些域,比如 author 和editor可能包含一些项的列表 (LIST)。这种列表结构由 BibTeX 文件格式通过关键词'and'实现,该关键词用例分隔列表中的各个独立项。Biblatex 包实现了三种不同的数据类型用于处理参考文献数据: 姓名列表 (name lists),逐字列表 (literal lists),和域 (fields)。同时也有几种列表的域的子类和一个内容类 (content),可以用来从语义上区分那些无法从它们的数据类进行区分的域(见§4.5.3)。本节给出包所支持的数据类的概览。更多的关于 BibTeX 文件格式域到 Biblatex 数据类型的映射信息参考 §§2.2.2 and 2.2.3 小节。

Name lists 对姓名列表解析能以 and 为间隔符分成为独立的项。列表中的每一项进一步剖析为 4 个名称的组成部分,the first name(西方人名的第一个字,对于中文来说,名字无需划分,如果是拼音的话,是可以对应的划分的),the name prefix (姓名前缀比如 von, van, of, da, de, della, ...),the last name(姓),the name suffix(名字后缀,比如 junior, senior, ...)。姓名列表在 bib 文件中可能会用关键词'and others' 截断。典型的姓名列表是author和editor。(译者注: 在些 bib 文件中参考文献数据的时候,当有些机构的名称中含有空格的情况下,最好将整个机构用 {} 包含起来。)

利用 Biber,在默认的数据模型中姓名列表自动进行一个\ifuse\*测试(见 § 4.6.2)。同时也自动创建了一个ifuse\*选项用例控制姓名的标记和排序行为(见 § 3.1.3.1)。

Biber only

Literal lists are parsed and split up into the individual items at the and delimiter but not dissected further. Literal lists may be truncated in the bib file with the keyword 'and others'. There are two subtypes:

逐字列表类似的解析并划分成独立的项,但不再进一步的剖析。逐字列表也 类似的被截断。它有两个子类:

**Literal lists** in the strict sense are handled as described above. The individual items are simply printed as is. Typical examples of such literal lists are publisher and location.

严格的按照上面的描述处理。各独立项简单如实打印。典型的逐字列表是publisher和 location。

**Key lists** are a variant of literal lists which may hold printable data or localization keys. For each item in the list, a test is performed to determine whether it is a known localization key (the localization keys defined by default are listed in § 4.9.2). If so, the localized string is printed. If not, the item is printed as is. A typical example of a key list is language.

关键词列表是逐字列表的变种,可以处理可打印的数据和本地化的关键词。对于列表中的每一项,首先执行测试它是否是已知的本地化关键词(本地化关键词默认定义在§4.9.2中)。如果是,那么打印本地化的字符串,否则如实打印。典型的关键词列表是language。

**Fields** are usually printed as a whole. There are several subtypes:

域是以整体打印的,有多种子类:

**Literal fields** are printed as is. Typical examples of literal fields are title and note.

逐字域,如实打印。典型的逐字域是title和note。

Range fields consist of one or more ranges where all dashes are normalized and replaced by the command \bibrangedash. A range is something optionally followed by one or more dashes optionally followed by some non-dash (e.g. 5-7). Any number of consecutive dashes will only yield a single range dash. A typical example of a range field is the pages field. See also the \bibrangessep command which can be used to customise the separator between multiple ranges. With Biber, range fields will be skipped and will generate a warning if they do not consist of one or more ranges. You can normalise messy range fields before they are parsed using \DeclareSourcemap (see § 4.5.2).

Biber only

范围域,包括一个或更多的范围,其中所有的短划线都规范化用命令\bibrangedash代替。一个范围是非短划线紧跟一个或多个短划线再跟上非短划线构成(比如 5-7)。任何有连续短划线的数字都将产生单个的范围短划线。典型的范围域是 pages域。\bibrangessep命令可以自定义多个范围之间的分隔符。利用 biber,范围域将跳过

Biber only

并产生一个警告信息当它不是由一个或多个范围组成。可以用使用\DeclareSourcemap命令在其被解析之前对其进行规范化(见 § 4.5.2)。

- Integer fields hold unformatted integers which may be converted to ordinals or strings as they are printed. A typical example is the extrayear field. 整数域,处理非格式化的整数,这些整数可以转化为序数或者字符串。典型的域有:extrayear。
- Datepart fields hold unformatted integers which may be converted to ordinals or strings as they are printed. A typical example is the month field. 部分日期域,处理非格式化的整数,这些整数可以转化为序数或者字符串。典型的域有:month。
- Date fields hold a date specification in yyyy-mm-dd format or a date range in yyyy-mm-dd/yyyy-mm-dd format. Date fields are special in that the date is parsed and split up into its components. See § 2.3.8 for details. A typical example is the date field.

日期域,处理一个以 yyyy-mm-dd 格式规定的日期或者一个以 yyyy-mm-dd/yyyy-mm-dd 格式规定的日期范围。日期域需要特别的解析并分成不同的部分。更多细节见 § 2.3.8 。典型的域有: date。

- **Verbatim fields** are processed in verbatim mode and may contain special characters. Typical examples of verbatim fields are file and doi. 字面(逐字)域,以 verbatim 模式处理可能包含特殊的字符,典型的字面(逐字)域有:file和 doi。
- **URI fields** are processed in verbatim mode and may contain special characters. They are also URL-escaped if they don't look like they already are. The typical example of a uri field is url.

url 域以 verbatim 模式处理,可能包含特殊的字符。如果它们看起来不像其实质,也可以例外处理。典型域是 url.

Separated value fields A separated list of literal values. Examples are the keywords and options fields. The separator is always a comma when using BibTeX as the backend but can be configured to be any Perl regular expression when using Biber via the xsvsep option which defaults to the usual BibTeX comma surrounded by optional whitespace.

分离值域,字母值的分离列表。典型的域是keywords和options。使用 BibTeX 后端时时分隔符总是逗号,但可以使用xsvsep选项重设为任何的 PERL 正则表达式,当使用 biber 后端时,当然默认情况下也是逗号或者逗号加空格。

**Pattern fields** A literal field which must match a particular pattern. An example is the gender field from § 2.2.3.

型(pattern)域,是逐字域必须匹配特殊的pattern。典型的域是gender,见§2.2.3。

**Key fields** May hold printable data or localization keys. A test is performed to determine whether the value of the field is a known localization key (the localization keys defined by default are listed in § 4.9.2). If so, the localized string is printed. If not, the value is printed as is. A typical example is the type field.

关键词域,可以处理可打印数据或本地化关键词。类似于逐字列表中 的关键词列表,这是这里是单个的域,而不是列表。

#### Code fields Holds TeX code.

代码 (code) 域,处理代码。

#### 2.2.2 数据域 Data Fields

The fields listed in this section are the regular ones holding printable data in the default data model. The name on the left is the default data model name of the field as used by Biblatex and its backend. The Biblatex data type is given to the right of the name. See § 2.2.1 for explanation of the various data types.

本节中列出的域是默认数据模型携带可打印数据的。左侧给出的名称是 Biblatex 及其后端中使用的域的默认数据模型名。而右侧给出的是它的数据类型。不同的数据类型的解释见 § 2.2.1。

Some fields are marked as 'Label fields' which means that they are often used as abbreviation labels when printing bibliography lists in the sense of section § 3.6.4. Biblatex automatically creates supporting macros for such fields. See § 3.6.4.

Biber only

一些以 'Label fields' 标记的域表示当以§ 3.6.4节的方式打印参考文献列表时 Biber only 它们常用为简化标签。Biblatex 自动创建支持这些域的宏,详见§ 3.6.4。

### abstract field (literal)

This field is intended for recording abstracts in a bib file, to be printed by a special bibliography style. It is not used by all standard bibliography styles.

标准样式不使用

## addendum field (literal)

Miscellaneous bibliographic data to be printed at the end of the entry. This is similar to the note field except that it is printed at the end of the bibliography entry.

## afterword list (name)

The author(s) of an afterword to the work. If the author of the afterword is identical to the editor and/or translator, the standard styles will automatically concatenate these fields in the bibliography. See also introduction and foreword.

后记的作者,当域编者或译者相同时,标准样式自动联接这些域。

annotation field (literal)

This field may be useful when implementing a style for annotated bibliographies. It is not used by all standard bibliography styles. Note that this field is completely unrelated to annotator. The annotator is the author of annotations which are part of the work cited.

标准样式不使用

annotator list (name)

The author(s) of annotations to the work. If the annotator is identical to the editor and/or translator, the standard styles will automatically concatenate these fields in the bibliography. See also commentator.

注释的作者,当与编者和译者同时,标准样式自动联接。

author list (name)

The author(s) of the title.

作者,姓名类

authortype field (key)

The type of author. This field will affect the string (if any) used to introduce the author. Not used by the standard bibliography styles.

标准样式不用

bookauthor list (name)

The author(s) of the booktitle.

书名作者,姓名类

bookpagination field (key)

If the work is published as part of another one, this is the pagination scheme of the enclosing work, i. e., bookpagination relates to pagination like booktitle to title. The value of this field will affect the formatting of the pages and pagetotal fields. The key should be given in the singular form. Possible keys are page, column, line, verse, section, and paragraph. See also pagination as well as § 2.3.10.

标记页数

booksubtitle field (literal)

The subtitle related to the booktitle. If the subtitle field refers to a work which is part of a larger publication, a possible subtitle of the main work is given in this field. See also subtitle.

工作的子标题

#### booktitle field (literal)

If the title field indicates the title of a work which is part of a larger publication, the title of the main work is given in this field. See also title.

书的标题,当 title 用来表示该书所在的更大的出版物的标题时用

### booktitleaddon field (literal)

An annex to the booktitle, to be printed in a different font.

附加标题

chapter field (literal)

A chapter or section or any other unit of a work.

章节名

## commentator list (name)

The author(s) of a commentary to the work. Note that this field is intended for commented editions which have a commentator in addition to the author. If the work is a stand-alone commentary, the commentator should be given in the author field. If the commentator is identical to the editor and/or translator, the standard styles will automatically concatenate these fields in the bibliography. See also annotator.

某工作的评论的作者,类似于annotator。

## date field (date)

The publication date. See also month and year as well as § 2.3.8.

出版日期。还可参见month, year和§2.3.8小节。

## doi field (verbatim)

The Digital Object Identifier of the work.

数字对象标识符。verbatim 类。

## edition field (integer or literal)

The edition of a printed publication. This must be an integer, not an ordinal. Don't say edition={First} or edition={1st} but edition={1}. The bibliography style converts this to a language dependent ordinal. It is also possible to give the edition as a literal string, for example "Third, revised and expanded edition".

版本域,整数或者逐字类。

#### editor list (name)

The editor(s) of the title, booktitle, or maintitle, depending on the entry type. Use the editortype field to specify the role if it is different from 'editor'. See § 2.3.6 for further hints.

编者,姓名类

#### editora list (name)

A secondary editor performing a different editorial role, such as compiling, redacting, etc. Use the editoratype field to specify the role. See § 2.3.6 for further hints.

editora,次要编者,比如汇集,编纂,修订等工作作者。

#### editorb list (name)

Another secondary editor performing a different role. Use the editorbtype field to specify the role. See § 2.3.6 for further hints.

editora,次要编者。

## editorc list (name)

Another secondary editor performing a different role. Use the editorctype field to specify the role. See § 2.3.6 for further hints.

editora, 次要编者。

#### editortype field (key)

The type of editorial role performed by the editor. Roles supported by default are editor, compiler, founder, continuator, redactor, reviser, collaborator. The role 'editor' is the default. In this case, the field is omissible. See § 2.3.6 for further hints.

编者类型,用于描述编者的角色。

## editoratype field (key)

Similar to editortype but referring to the editora field. See § 2.3.6 for further hints.

editoratype,次要编者类型,用于描述编者的角色。

## editorbtype field (key)

Similar to editortype but referring to the editorb field. See § 2.3.6 for further hints.

editorbtype,次要编者类型,用于描述编者的角色。

## editorctype field (key)

Similar to editortype but referring to the editorc field. See § 2.3.6 for further hints.

editorctype,次要编者类型,用于描述编者的角色。

## eid field (literal)

The electronic identifier of an @article.

文章电子 ID 号。

## entrysubtype field (literal)

This field, which is not used by the standard styles, may be used to specify a subtype of an entry type. This may be useful for bibliography styles which support a finer-grained set of entry types.

标准样式不用。

## eprint field (verbatim)

The electronic identifier of an online publication. This is roughly comparable to a dol but specific to a certain archive, repository, service, or system. See § 3.11.7 for details. Also see eprinttype and eprintclass.

在线出版物的电子 ID 号。

## eprintclass field (literal)

Additional information related to the resource indicated by the eprinttype field. This could be a section of an archive, a path indicating a service, a classification of some sort, etc. See § 3.11.7 for details. Also see eprint and eprinttype.

eprinttype 域的附加信息。

## eprinttype field (literal)

The type of eprint identifier, e.g., the name of the archive, repository, service, or system the eprint field refers to. See § 3.11.7 for details. Also see eprint and eprintclass.

eprint 域的类型信息。比如档案,仓库,服务,系统的名字。

## eventdate field (date)

The date of a conference, a symposium, or some other event in @proceedings and @inproceedings entries. This field may also be useful for the custom types listed in § 2.1.3. See also eventtitle and venue as well as § 2.3.8.

一些如会议, 专题讨论, 座谈等事件的日期。

## eventtitle field (literal)

The title of a conference, a symposium, or some other event in <code>@proceedings</code> and <code>@inproceedings</code> entries. This field may also be useful for the custom types listed in § 2.1.3. Note that this field holds the plain title of the event. Things like "Proceedings of the Fifth XYZ Conference" go into the <code>titleaddon</code> or <code>booktitleaddon</code> field, respectively. See also <code>eventdate</code> and <code>venue</code>.

## eventtitleaddon field (literal)

An annex to the eventtitle field. Can be used for known event acronyms, for example.

#### file field (verbatim)

A local link to a PDF or other version of the work. Not used by the standard bibliography styles.

标准样式不使用

## foreword list (name)

The author(s) of a foreword to the work. If the author of the foreword is identical to the editor and/or translator, the standard styles will automatically concatenate these fields in the bibliography. See also introduction and afterword.

前言作者。

## holder list (name)

The holder(s) of a @patent, if different from the author. Not that corporate holders need to be wrapped in an additional set of braces, see § 2.3.3 for details. This list may also be useful for the custom types listed in § 2.1.3.

专利持有人。

#### howpublished field (literal)

A publication notice for unusual publications which do not fit into any of the common categories.

非常规出版物的出版信息。

#### indextitle field (literal)

A title to use for indexing instead of the regular title field. This field may be useful if you have an entry with a title like "An Introduction to ..." and want that indexed as "Introduction to ..., An". Style authors should note that Biblatex automatically copies the value of the title field to indextitle if the latter field is undefined.

## institution list (literal)

The name of a university or some other institution, depending on the entry type. Traditional BibTeX uses the field name school for theses, which is supported as an alias. See also §§ 2.2.5 and 2.3.4.

大学或研究机构, bibtex 中使用的域名是 school。

#### introduction list (name)

The author(s) of an introduction to the work. If the author of the introduction is identical to the editor and/or translator, the standard styles will automatically concatenate these fields in the bibliography. See also foreword and afterword.

简介的作者。

## isan field (literal)

The International Standard Audiovisual Number of an audiovisual work. Not used by the standard bibliography styles.

ISAN号。

isbn field (literal)

The International Standard Book Number of a book.

ISBN号。

ismn field (literal)

The International Standard Music Number for printed music such as musical scores. Not used by the standard bibliography styles.

ISMN号。

isrn field (literal)

The International Standard Technical Report Number of a technical report.

ISRN号。

issn field (literal)

The International Standard Serial Number of a periodical.

ISSN号。

issue field (literal)

The issue of a journal. This field is intended for journals whose individual issues are identified by a designation such as 'Spring' or 'Summer' rather than the month or a number. Since the placement of issue is similar to month and number, this field may also be useful with double issues and other special cases. See also month, number, and § 2.3.9.

期刊的版次,通常是特殊的版次,而不是以月份和数字标示的版次。(译者注:可能类似于什么什么增刊,特刊等。)

issuesubtitle field (literal)

The subtitle of a specific issue of a journal or other periodical.

issuetitle field (literal)

The title of a specific issue of a journal or other periodical.

iswc field (literal)

The International Standard Work Code of a musical work. Not used by the standard bibliography styles.

ISWC 码。

## journalsubtitle field (literal)

The subtitle of a journal, a newspaper, or some other periodical.

期刊等周期出版物的子名

## journaltitle field (literal)

The name of a journal, a newspaper, or some other periodical.

期刊等周期出版物的名

#### label field (literal)

A designation to be used by the citation style as a substitute for the regular label if any data required to generate the regular label is missing. For example, when an author-year citation style is generating a citation for an entry which is missing the author or the year, it may fall back to label. See § 2.3.2 for details. Note that, in contrast to shorthand, label is only used as a fallback. See also shorthand.

## language list (key)

The language(s) of the work. Languages may be specified literally or as localization keys. If localization keys are used, the prefix lang is omissible. See also originanguage and compare langid in § 2.2.3.

工作的语言。

## library field (literal)

This field may be useful to record information such as a library name and a call number. This may be printed by a special bibliography style if desired. Not used by the standard bibliography styles.

标准样式不用。

## location list (literal)

The place(s) of publication, i. e., the location of the publisher or institution, depending on the entry type. Traditional BibTeX uses the field name address, which is supported as an alias. See also §§ 2.2.5 and 2.3.4. With @patent entries, this list indicates the scope of a patent. This list may also be useful for the custom types listed in § 2.1.3.

出版社地址。

## mainsubtitle field (literal)

The subtitle related to the maintitle. See also subtitle.

#### maintitle field (literal)

The main title of a multi-volume book, such as *Collected Works*. If the title or booktitle field indicates the title of a single volume which is part of multi-volume book, the title of the complete work is given in this field.

集合物的名称,当 title 指单卷物的时候用。

maintitleaddon field (literal)

An annex to the maintitle, to be printed in a different font.

month field (datepart)

The publication month. This must be an integer, not an ordinal or a string. Don't say month={January} but month={1}. The bibliography style converts this to a language dependent string or ordinal where required. See also date as well as §§ 2.3.9 and 2.3.8.

出版月份。

nameaddon field (literal)

An addon to be printed immediately after the author name in the bibliography. Not used by the standard bibliography styles. This field may be useful to add an alias or pen name (or give the real name if the pseudonym is commonly used to refer to that author).

标准样式不用。

note field (literal)

Miscellaneous bibliographic data which does not fit into any other field. The note field may be used to record bibliographic data in a free format. Publication facts such as "Reprint of the edition London 1831" are typical candidates for the note field. See also addendum.

混杂数据, 无法分类到某一种域中。

number field (literal)

The number of a journal or the volume/number of a book in a series. See also issue as well as §§ 2.3.7 and 2.3.9. With @patent entries, this is the number or record token of a patent or patent request.

期刊或数的卷的数字号比如期号。在专利条目中是专利申请号。

organization list (literal)

The organization(s) that published a @manual or an @online resource, or sponsored a conference. See also § 2.3.4.

手册或在线资源或会议主办的机构。

origdate field (date)

If the work is a translation, a reprint, or something similar, the publication date of the original edition. Not used by the standard bibliography styles. See also date.

标准样式不用。

origlanguage field (key)

If the work is a translation, the language of the original work. See also language.

origlocation list (literal)

If the work is a translation, a reprint, or something similar, the location of the original edition. Not used by the standard bibliography styles. See also location and § 2.3.4.

origpublisher list (literal)

If the work is a translation, a reprint, or something similar, the publisher of the original edition. Not used by the standard bibliography styles. See also publisher and § 2.3.4.

origtitle field (literal)

If the work is a translation, the title of the original work. Not used by the standard bibliography styles. See also title.

pages field (range)

One or more page numbers or page ranges. If the work is published as part of another one, such as an article in a journal or a collection, this field holds the relevant page range in that other work. It may also be used to limit the reference to a specific part of a work (a chapter in a book, for example).

页码范围。

pagetotal field (literal)

The total number of pages of the work.

总页数。

pagination field (key)

The pagination of the work. The value of this field will affect the formatting the  $\langle postnote \rangle$  argument to a citation command. The key should be given in the singular form. Possible keys are page, column, line, verse, section, and paragraph. See also bookpagination as well as §§ 2.3.10 and 3.12.3.

## part field (literal)

The number of a partial volume. This field applies to books only, not to journals. It may be used when a logical volume consists of two or more physical ones. In this case the number of the logical volume goes in the volume field and the number of the part of that volume in the part field. See also volume.

卷的部分的号。

publisher list (literal)

The name(s) of the publisher(s). See also § 2.3.4.

出版社名。

pubstate field (key)

The publication state of the work, e.g., 'in press'. See § 4.9.2.11 for known publication states.

出版状态。

reprinttitle field (literal)

The title of a reprint of the work. Not used by the standard styles.

BibTeX only

标准样式不用。

series field (literal)

The name of a publication series, such as "Studies in ...", or the number of a journal series. Books in a publication series are usually numbered. The number or volume of a book in a series is given in the number field. Note that the @article entry type makes use of the series field as well, but handles it in a special way. See § 2.3.7 for details.

系列丛书的标题。

shortauthor list (name)

Label field

The author(s) of the work, given in an abbreviated form. This field is mainly intended for abbreviated forms of corporate authors, see § 2.3.3 for details.

缩略的作者名。

shorteditor list (name)

Label field

The editor(s) of the work, given in an abbreviated form. This field is mainly intended for abbreviated forms of corporate editors, see § 2.3.3 for details.

缩略的编者名。

shorthand field (literal)

Label field

A special designation to be used by the citation style instead of the usual label. If defined, it overrides the default label. See also label.

特殊标记用于引用样式代替常用的标签。

shorthandintro field (literal)

The verbose citation styles which comes with this package use a phrase like "hence-forth cited as [shorthand]" to introduce shorthands on the first citation. If the shorthandintro field is defined, it overrides the standard phrase. Note that the alternative phrase must include the shorthand.

shortjournal field (literal)

Label field

A short version or an acronym of the journaltitle. Not used by the standard bibliography styles.

期刊名首字母缩略词。

shortseries field (literal)

Label field

A short version or an acronym of the series field. Not used by the standard bibliography styles.

shorttitle field (literal)

Label field

The title in an abridged form. This field is usually not included in the bibliography. It is intended for citations in author-title format. If present, the author-title citation styles use this field instead of title.

subtitle field (literal)

The subtitle of the work.

工作的子标题。

title field (literal)

The title of the work.

工作的标题。

titleaddon field (literal)

An annex to the title, to be printed in a different font.

translator list (name)

The translator(s) of the title or booktitle, depending on the entry type. If the translator is identical to the editor, the standard styles will automatically concatenate these fields in the bibliography.

译者。

```
type field (key)
```

The type of a manual, patent, report, or thesis. This field may also be useful for the custom types listed in  $\S 2.1.3$ .

类型。

url field (url)

The URL of an online publication. If it is not URL-escaped (no '%' chars), with Biber, it will be URI-escaped according to RFC 3987, that is, even Unicode chars will be correctly escaped.

url.

urldate field (date)

The access date of the address specified in the url field. See also § 2.3.8.

venue field (literal)

The location of a conference, a symposium, or some other event in <code>@proceedings</code> and <code>@inproceedings</code> entries. This field may also be useful for the custom types listed in § 2.1.3. Note that the <code>location</code> list holds the place of publication. It therefore corresponds to the <code>publisher</code> and <code>institution</code> lists. The location of the event is given in the <code>venue</code> field. See also <code>eventdate</code> and <code>eventtitle</code>.

现场。会议, 座谈, 或其它事件的地址。

version field (literal)

The revision number of a piece of software, a manual, etc.

版本。

volume field (literal)

The volume of a multi-volume book or a periodical. See also part.

期刊或多卷书的卷的卷数。

volumes field (literal)

The total number of volumes of a multi-volume work. Depending on the entry type, this field refers to title or maintitle.

总卷数。

year field (literal)

The year of publication. See also date and § 2.3.8.

年份。

## 2.2.3 特殊域 Special Fields

The fields listed in this section do not hold printable data but serve a different purpose. They apply to all entry types in the default data model.

本节中的域不包括可打印的数据,用于其它用途,可用于默认数据模型的所 有条目类型。

## crossref field (entry key)

This field holds an entry key for the cross-referencing feature. Child entries with a crossref field inherit data from the parent entry specified in the crossref field. If the number of child entries referencing a specific parent entry hits a certain threshold, the parent entry is automatically added to the bibliography even if it has not been cited explicitly. The threshold is settable with the mincrossrefs package option from § 3.1.2.1. Style authors should note that whether or not the crossref fields of the child entries are defined on the Biblatex level depends on the availability of the parent entry. If the parent entry is available, the crossref fields of the child entries will be defined. If not, the child entries still inherit the data from the parent entry but their crossref fields will be undefined. Whether the parent entry is added to the bibliography implicitly because of the threshold or explicitly because it has been cited does not matter. See also the xref field in this section as well as § 2.4.1.

## entryset field (separated values)

This field is specific to entry sets. See § 3.11.5 for details. This field is consumed by the backend processing and does not appear in the .bbl.

#### execute field (code)

A special field which holds arbitrary TeX code to be executed whenever the data of the respective entry is accessed. This may be useful to handle special cases. Conceptually, this field is comparable to the hooks \AtEveryBibitem, \AtEveryLositem, and \AtEveryCitekey from § 4.10.6, except that it is definable on a per-entry basis in the bib file. Any code in this field is executed automatically immediately after these hooks.

## gender field (Pattern matching one of: sf, sm, sn, pf, pm, pn, pp)

The gender of the author or the gender of the editor, if there is no author. The following identifiers are supported: sf (feminine singular, a single female name), sm (masculine singular, a single male name), sn (neuter singular, a single neuter name), pf (feminine plural, a list of female names), pm (masculine plural, a list of male names), pn (neuter plural, a list of neuter names), pp (plural, a mixed gender list of names). This information is only required by special bibliography and citation styles and only in certain languages. For example, a citation style may replace recurrent author names with a term such as 'idem'. If the Latin word is used, as is custom in English and French, there

Language	Region/Dialect	Identifiers
Catalan	Spain, France, Andorra, Italy	catalan
Croatian	Croatia, Bosnia and Herzegovina, Serbia	croatian
Czech	Czech Republic	czech
Danish	Denmark	danish
Dutch	Netherlands	dutch
English	USA	american, USenglish, english
	United Kingdom	british, UKenglish
	Canada	canadian
	Australia	australian
	New Zealand	newzealand
Finnish	Finland	finnish
French	France, Canada	french
German	Germany	german
	Austria	austrian
German (new)	Germany	ngerman
	Austria	naustrian
Greek	Greece	greek
Italian	Italy	italian
Norwegian	Norway	norwegian, norsk, nynorsk
Polish	Poland	polish
Portuguese	Brazil	brazil
	Portugal	portuguese, portuges
Russian	Russia	russian
Slovene	Slovenian	slovene
Spanish	Spain	spanish
Swedish	Sweden	swedish

**Table 2: Supported Languages** 

34

is no need to specify the gender. In German publications, however, such key terms are usually given in German and in this case they are gender-sensitive.

## langid field (identifier)

The language id of the bibliography entry. The alias hyphenation is provided for backwards compatibility. The identifier must be a language name known to the babel/polyglossia packages. This information may be used to switch hyphenation patterns and localize strings in the bibliography. Note that the language names are case sensitive. The languages currently supported by this package are given in table 2. Note that babel treats the identifier english as an alias for british or american, depending on the babel version. The Biblatex package always treats it as an alias for american. It is preferable to use the language identifiers american and british (babel) or a language specific option to specify a language variant (polyglossia, using the languagets field) to avoid any possible confusion. Compare language in § 2.2.2.

## langidopts field (literal)

For polyglossia users, allows per-entry language specific options. The literal value of this field is passed to polyglossia's language switching facility when using the package option autolang=langname. For example, the fields:

```
langid = {english},
langidopts = {variant=british},
```

would wrap the bibliography entry in:

```
\english[variant=british]
...
\endenglish
```

## ids field (separated list of entrykeys)

Biber only

Citation key aliases for the main citation key. An entry may be cited by any of its aliases and Biblatex will treat the citation as if it had used the primary citation key. This is to aid users who change their citation keys but have legacy documents which use older keys for the same entry. This field is consumed by the backend processing and does not appear in the .bbl.

#### indexsorttitle field (literal)

The title used when sorting the index. In contrast to indextitle, this field is used for sorting only. The printed title in the index is the indextitle or the title field. This field may be useful if the title contains special characters or commands which interfere with the sorting of the index. Consider this example:

```
title = {The \LaTeX\ Companion},
indextitle = {\LaTeX\ Companion, The},
indexsorttitle = {LATEX Companion},
```

Style authors should note that Biblatex automatically copies the value of either the indextitle or the title field to indexsorttitle if the latter field is undefined.

keywords field (separated values)

A separated list of keywords. These keywords are intended for the bibliography filters (see §§ 3.6.2 and 3.11.4), they are usually not printed. Note that with the default separator (comma), spaces around the separator are ignored.

options field (separated  $\langle key \rangle = \langle value \rangle$  options)

A separated list of entry options in  $\langle key \rangle = \langle value \rangle$  notation. This field is used to set options on a per-entry basis. See § 3.1.3 for details. Note that citation and bibliography styles may define additional entry options.

presort field (string)

A special field used to modify the sorting order of the bibliography. This field is the first item the sorting routine considers when sorting the bibliography, hence it may be used to arrange the entries in groups. This may be useful when creating subdivided bibliographies with the bibliography filters. Please refer to § 3.5 for further details. Also see § 4.5.5. This field is consumed by the backend processing and does not appear in the .bbl.

related field (separated values)

Biber only

Citation keys of other entries which have a relationship to this entry. The relationship is specified by the relatedtype field. Please refer to § 3.4 for further details.

relatedoptions fie

field (separated values)

Biber only

Per-type options to set for a related entry. Note that this does not set the options on the related entry itself, only the dataonly clone which is used as a datasource for the parent entry.

relatedtype

field (identifier)

Biber only

An identifier which specified the type of relationship for the keys listed in the related field. The identifier is a localized bibliography string printed before the data from the related entry list. It is also used to identify type-specific formatting directives and bibliography macros for the related entries. Please refer to § 3.4 for further details.

relatedstring field (literal)

Biber only

A field used to override the bibliography string specified by relatedtype. Please refer to § 3.4 for further details.

#### sortkey field (literal)

A field used to modify the sorting order of the bibliography. Think of this field as the master sort key. If present, Biblatex uses this field during sorting and ignores everything else, except for the presort field. Please refer to § 3.5 for further details. This field is consumed by the backend processing and does not appear in the .bbl.

sortname list (name)

A name or a list of names used to modify the sorting order of the bibliography. If present, this list is used instead of author or editor when sorting the bibliography. Please refer to § 3.5 for further details. This field is consumed by the backend processing and does not appear in the .bbl.

sortshorthand field (literal)

Biber only

Similar to sortkey but used in the list of shorthands. If present, Biblatex uses this field instead of shorthand when sorting the list of shorthands. This is useful if the shorthand field holds shorthands with formatting commands such as \emph or \textbf. This field is consumed by the backend processing and does not appear in the .bbl.

sorttitle field (literal)

A field used to modify the sorting order of the bibliography. If present, this field is used instead of the title field when sorting the bibliography. The sorttitle field may come in handy if you have an entry with a title like "An Introduction to..." and want that alphabetized under 'I' rather than 'A'. In this case, you could put "Introduction to..." in the sorttitle field. Please refer to § 3.5 for further details. This field is consumed by the backend processing and does not appear in the .bbl.

sortyear field (literal)

A field used to modify the sorting order of the bibliography. If present, this field is used instead of the year field when sorting the bibliography. Please refer to § 3.5 for further details. This field is consumed by the backend processing and does not appear in the .bbl.

xdata field (separated list of entrykeys)

Biber only

This field inherits data from one or more @xdata entries. Conceptually, the xdata field is related to crossref and xref: crossref establishes a logical parent/child relation and inherits data; xref establishes as logical parent/child relation without inheriting data; xdata inherits data without establishing a relation. The value of the xdata may be a single entry key or a separated list of keys. See § 3.11.6 for further details. This field is consumed by the backend processing and does not appear in the .bb1.

#### xref field (entry key)

This field is an alternative cross-referencing mechanism. It differs from crossref in that the child entry will not inherit any data from the parent entry specified in the xref field. If the number of child entries referencing a specific parent entry hits a certain threshold, the parent entry is automatically added to the bibliography even if it has not been cited explicitly. The threshold is settable with the mincrossrefs package option from § 3.1.2.1. Style authors should note that whether or not the xref fields of the child entries are defined on the Biblatex level depends on the availability of the parent entry. If the parent entry is available, the xref fields of the child entries will be defined. If not, their xref fields will be undefined. Whether the parent entry is added to the bibliography implicitly because of the threshold or explicitly because it has been cited does not matter. See also the crossref field in this section as well as § 2.4.1.

#### 2.2.4 自定义域 Custom Fields

The fields listed in this section are intended for special bibliography styles. They are not used by the standard bibliography styles.

本节中的域用于特定的参考文献样式、标准样式不使用。

name[a-c] list (name)

Custom lists for special bibliography styles. Not used by the standard bibliography styles.

name[a-c]type field (key)

Similar to authortype and editortype but referring to the fields name [a-c]. Not used by the standard bibliography styles.

list[a-f] list (literal)

Custom lists for special bibliography styles. Not used by the standard bibliography styles.

user[a-f] field (literal)

Custom fields for special bibliography styles. Not used by the standard bibliography styles.

verb[a-c] field (literal)

Similar to the custom fields above except that these are verbatim fields. Not used by the standard bibliography styles.

#### 2.2.5 域的别名 Field Aliases

The aliases listed in this section are provided for backwards compatibility with traditional BibTeX and other applications based on traditional BibTeX styles. Note that these aliases are immediately resolved as the bib file is processed. All bibliography and citation styles must use the names of the fields they point to, not the alias. In bib files, you may use either the alias or the field name but not both at the same time.

本级列出的别名用于兼容传统的 bibtex。在 biblatex 的样式文件中则必须使用这些别名所指代的域名。

#### address list (literal)

An alias for location, provided for BibTeX compatibility. Traditional BibTeX uses the slightly misleading field name address for the place of publication, i. e., the location of the publisher, while Biblatex uses the generic field name location. See §§ 2.2.2 and 2.3.4.

address 就是 location。

annote field (literal)

An alias for annotation, provided for jurabib compatibility. See § 2.2.2.

archiveprefix field (literal)

An alias for eprinttype, provided for arXiv compatibility. See §§ 2.2.2 and 3.11.7.

journal field (literal)

An alias for journaltitle, provided for BibTeX compatibility. See § 2.2.2. journal 就是 journaltitle。

key field (literal)

An alias for sortkey, provided for BibTeX compatibility. See § 2.2.3.

key 是 sortkey。

pdf field (verbatim)

An alias for file, provided for JabRef compatibility. See § 2.2.2.

pdf 是 file。

primaryclass field (literal)

An alias for eprintclass, provided for arXiv compatibility. See §§ 2.2.2 and 3.11.7.

school list (literal)

An alias for institution, provided for BibTeX compatibility. The institution field is used by traditional BibTeX for technical reports whereas the school field holds

the institution associated with theses. The Biblatex package employs the generic field name institution in both cases. See §§ 2.2.2 and 2.3.4.

school 是 institution。

# 2.3 使用注意事项 Usage Notes

The entry types and fields supported by this package should for the most part be intuitive to use for anyone familiar with BibTeX. However, apart from the additional types and fields provided by this package, some of the familiar ones are handled in a way which is in need of explanation.

本包支持的类型和域对于熟悉 bibtex 的人来说可以直觉的使用。然而除了传统的类型和域,其中某些熟悉的域和类型需要进一步解释。

This package includes some compatibility code for bib files which were generated with a traditional BibTeX style in mind. Unfortunately, it is not possible to handle all legacy files automatically because Biblatex's data model is slightly different from traditional BibTeX. Therefore, such bib files will most likely require editing in order to work properly with this package. In sum, the following items are different from traditional BibTeX styles:

本包包含了一些兼容 bibtex 的代码,但不可能完全处理所有的继承 bib 文件,因此这些 bib 需要修改,一些不同的需要修改的地方,总结如下:

- The entry type @inbook. See §§ 2.1.1 and 2.3.1 for details.
- The fields institution, organization, and publisher as well as the aliases address and school. See §§ 2.2.2, 2.2.5, 2.3.4 for details.
- The handling of certain types of titles. See § 2.3.5 for details.
- The field series. See §§ 2.2.2 and 2.3.7 for details.
- The fields year and month. See §§ 2.2.2, 2.3.8, 2.3.9 for details.
- The field edition. See § 2.2.2 for details.
- The field key. See § 2.3.2 for details.

Users of the jurabib package should note that the shortauthor field is treated as a name list by Biblatex, see § 2.3.3 for details.

#### 2.3.1 @inbook条目类型 The Entry Type @inbook

@inbook条目类型只用来表示以书籍 (专著) 中包含的某一具有标题的部分作为引文的参考文献。它与 @book的关系如同@incollection和@collection的关系。具体示例见 § 2.3.5。如果只是将书籍的章节作为引文,简单的使用book类型再加上chapter 和/or pages 域即可。至于参考文献列表是否应该完全包含章节引文的问题是有争议的,因为章并不是一个参考文献实体。

## 2.3.2 缺失和可忽略数据 Missing and Omissible Data

The fields marked as 'required' in § 2.1.1 are not strictly required in all cases. The bibliography styles which ship with this package can get by with as little as a title field for most entry types. A book published anonymously, a periodical without an explicit editor, or a software manual without an explicit author should pose no problem as far as the bibliography is concerned. Citation styles, however, may have different requirements. For example, an author-year citation scheme obviously requires an author/editor and a year field.

You may generally use the label field to provide a substitute for any missing data required for citations. How the label field is employed depends on the citation style. The author-year citation styles which come with this package use the label field as a fallback if either the author/editor or the year is missing. The numeric styles, on the other hand, do not use it at all since the numeric scheme is independent of the available data. The author-title styles ignore it as well, because the bare title is usually sufficient to form a unique citation and a title is expected to be available in any case. The label field may also be used to override the non-numeric portion of the automatically generated labelalpha field used by alphabetic citation styles. See § 4.2.4 for details.

Note that traditional BibTeX styles support a key field which is used for alphabetizing if both author and editor are missing. The Biblatex package treats key as an alias for sortkey. In addition to that, it offers very fine-grained sorting controls, see §§ 2.2.3 and 3.5 for details. The natbib package employs the key field as a fallback label for citations. Use the label field instead.

#### 2.3.3 集体作者和编者 Corporate Authors and Editors

Corporate authors and editors are given in the author or editor field, respectively. Note that they must be wrapped in an extra pair of curly braces to prevent data parsing from treating them as personal names which are to be dissected into their components. Use the shortauthor field if you want to give an abbreviated form of the name or an acronym for use in citations.

```
author = {{National Aeronautics and Space Administration}},
shortauthor = {NASA},
```

The default citation styles will use the short name in all citations while the full name is printed in the bibliography. For corporate editors, use the corresponding fields editor and shorteditor. Since all of these fields are treated as name lists, it is possible to mix personal names and corporate names, provided that the names of all corporations and institutions are wrapped in braces.

Users switching from the jurabib package to Biblatex should note that the shortauthor field is treated as a name list.

#### 2.3.4 原样输出列表 Literal Lists

The fields institution, organization, publisher, and location are literal lists in terms of § 2.2. This also applies to origlocation, origpublisher and to the field aliases address and school. All of these fields may contain a list of items separated by the keyword 'and'. If they contain a literal 'and', it must be wrapped in braces.

Note the difference between a literal '{and}' and the list separator 'and' in the above examples. You may also wrap the entire name in braces:

Legacy files which have not been updated for use with Biblatex will still work if these fields do not contain a literal 'and'. However, note that you will miss out on the additional features of literal lists in this case, such as configurable formatting and automatic truncation.

## 2.3.5 **题名 Titles**

The following examples demonstrate how to handle different types of titles. Let's start with a five-volume work which is referred to as a whole:

```
@MvBook{works,
  author = {Shakespeare, William},
  title = {Collected Works},
  volumes = {5},
  ...
```

The individual volumes of a multi-volume work usually have a title of their own. Suppose the fourth volume of the *Collected Works* includes Shakespeare's sonnets and we are referring to this volume only:

```
@Book{works:4,
  author = {Shakespeare, William},
  maintitle = {Collected Works},
  title = {Sonnets},
  volume = {4},
```

If the individual volumes do not have a title, we put the main title in the title field and include a volume number:

In the next example, we are referring to a part of a volume, but this part is a self-contained work with its own title. The respective volume also has a title and there is still the main title of the entire edition:

```
@InBook{lear,
  author = {Shakespeare, William},
  bookauthor = {Shakespeare, William},
  maintitle = {Collected Works},
  booktitle = {Tragedies},
  title = {King Lear},
  volume = {1},
  pages = {53-159},
  ...
```

Suppose the first volume of the *Collected Works* includes a reprinted essay by a well-known scholar. This is not the usual introduction by the editor but a self-contained work. The *Collected Works* also have a separate editor:

See § 2.3.7 for further examples.

#### 2.3.6 编辑角色 Editorial Roles

The type of editorial role performed by an editor in one of the editor fields (i. e., editor, editora, editorb, editorc) may be specified in the corresponding editor...type field. The following roles are supported by default. The role 'editor' is the default. In this case, the editortype field is omissible.

editor The main editor. This is the most generic editorial role and the default value.

compiler Similar to editor but used if the task of the editor is mainly compiling.

founder The founding editor of a periodical or a comprehensive publication project such as a 'Collected Works' edition or a long-running legal commentary.

continuator An editor who continued the work of the founding editor (founder) but was subsequently replaced by the current editor (editor).

redactor A secondary editor whose task is redacting the work.

reviser A secondary editor whose task is revising the work.

collaborator A secondary editor or a consultant to the editor.

For example, if the task of the editor is compiling, you may indicate that in the corresponding editortype field:

```
@Collection{...,
  editor = {Editor, Edward},
  editortype = {compiler},
  ...
```

There may also be secondary editors in addition to the main editor:

```
@Book{...,
  author = {...},
  editor = {Editor, Edward},
  editora = {Redactor, Randolph},
  editoratype = {redactor},
  editorb = {Consultant, Conrad},
  editorbtype = {collaborator},
  ...
```

Periodicals or long-running publication projects may see several generations of editors. For example, there may be a founding editor in addition to the current editor:

```
@Book{...,
  author = {...},
  editor = {Editor, Edward},
  editora = {Founder, Frederic},
  editoratype = {founder},
```

Note that only the editor is considered in citations and when sorting the bibliography. If an entry is typically cited by the founding editor (and sorted accordingly in the bibliography), the founder goes into the editor field and the current editor moves to one of the editor... fields:

```
@Collection{...,
  editor = {Founder, Frederic},
  editortype = {founder},
  editora = {Editor, Edward},
```

You may add more roles by initializing and defining a new localization key whose name corresponds to the identifier in the editor...type field. See §§ 3.8 and 4.9.1 for details.

## 2.3.7 出版物和期刊系列 Publication and Journal Series

The series field is used by traditional BibTeX styles both for the main title of a multi-volume work and for a publication series, i. e., a loosely related sequence of books by the same publisher which deal with the same general topic or belong to the same field of research. This may be ambiguous. This package introduces a maintitle field for multi-volume works and employs series for publication series only. The volume or number of a book in the series goes in the number field in this case:

```
@Book{...,
author = {Expert, Edward},
title = {Shakespeare and the Elizabethan Age},
series = {Studies in English Literature and Drama},
number = {57},
```

The @article entry type makes use of the series field as well, but handles it in a special way. First, a test is performed to determine whether the value of the field is an integer. If so, it will be printed as an ordinal. If not, another test is performed to determine whether it is a localization key. If so, the localized string is printed. If not, the value is printed as is. Consider the following example of a journal published in numbered series:

<b>Date Specification</b>	Formatted Date (Examples)			
	Short Format	Long Format		
1850	1850	1850		
1997/	1997-	1997-		
1967-02	02/1967	February 1967		
2009-01-31	31/01/2009	31st January 2009		
1988/1992	1988-1992	1988-1992		
2002-01/2002-02	01/2002-02/2002	January 2002–February 2002		
1995-03-30/1995-04-05	30/03/1995-05/04/1995	30th March 1995–5th April 1995		

**Table 3: Date Specifications** 

This entry will be printed as "Journal Name. 3rd ser. 15.7 (1995)". Some journals use designations such as "old series" and "new series" instead of a number. Such designations may be given in the series field as well, either as a literal string or as a localization key. Consider the following example which makes use of the localization key newseries:

This entry will be printed as "Journal Name. New ser. 9 (1998)". See § 4.9.2 for a list of localization keys defined by default.

#### 2.3.8 日期格式 Date Specifications

The date fields date, origdate, eventdate, and urldate require a date specification in yyyy-mm-dd format. Date ranges are given as yyyy-mm-dd/yyyy-mm-dd. Partial dates are valid provided that date components are omitted at the end only. You may specify an open ended date range by giving the range separator and omitting the end date (e.g., yyyy/). See table 3 for some examples of valid date specifications and the formatted date automatically generated by Biblatex. The formatted date is language specific and will be adapted automatically. If there is no date field in an entry, Biblatex will also consider the fields year and month for backwards compatibility with traditional BibTeX. Style author should note that date fields like date or origdate are only available in the bib file. All dates are parsed and dissected into their components as the bib file is processed. The date components are made available to styles by way of the special fields discussed in § 4.2.4.3. See this section and table 8 on page 159 for further information.

#### 2.3.9 月份和期刊季度号 Months and Journal Issues

The month field is an integer field. The bibliography style converts the month to a language-dependent string as required. For backwards compatibility, you may also use the following three-letter abbreviations in the month field: jan, feb, mar, apr, may, jun, jul, aug, sep, oct, nov, dec. Note that these abbreviations are BibTeX strings which must be given without any braces or quotes. When using them, don't say month={jan} or month="jan" but month=jan. It is not possible to specify a month such as month={8/9}. Use the date field for date ranges instead.

用于区分季刊的'Spring' 或'Summer' 应该放在issue域内,@article条目的issue域位置类似于month域并覆盖该域。

#### 2.3.10 标记页码 Pagination

当在条目的pages域或者一个引用命令的《postnote》参数中指定页码或者页码范围,很方便让 Biblatex 自动添加像 'p.' 或 'pp.' 之类的前缀,这也是该包的默认处理方式。然而,一些文档可能使用一种不同的页码标记格式或者可能不是以页码而是以诗节号或者行号为标记。这时pagination和bookpagination 域就可以起到作用了,举例考虑下面的条目:

The bookpagination field affects the formatting of the pages and pagetotal fields in the list of references. Since page is the default, this field is omissible in the above example. In this case, the page range will be formatted as 'pp. 53–65'. Suppose that, when quoting from this work, it is customary to use verse numbers rather than page numbers in citations. This is reflected by the pagination field, which affects the formatting of the  $\langle postnote \rangle$  argument to any citation command. With a citation like cite[17] {key}, the postnote will be formatted as 'v. 17'. Setting the pagination field to section would yield '§ 17'. See § 3.12.3 for further usage instructions.

The pagination and bookpagination fields are key fields. This package will try to use their value as a localization key, provided that the key is defined. Always use the singular form of the key name in bib files, the plural is formed automatically. The keys page, column, line, verse, section, and paragraph are predefined, with page being the default. The string 'none' has a special meaning when used in a pagination or bookpagination field. It suppresses the prefix for the respective entry. If there are no predefined localization keys for the pagination scheme required by a certain entry, you can simply add them. See the com-

mands \NewBibliographyString and \DefineBibliographyStrings in § 3.8. You need to define two localization strings for each additional pagination scheme: the singular form (whose localization key corresponds to the value of the pagination field) and the plural form (whose localization key must be the singular plus the letter 's'). See the predefined keys in § 4.9.2 for examples.

## 2.4 提示与警告 Hints and Caveats

This section provides some additional hints concerning the data interface of this package. It also addresses some common problems.

## 2.4.1 交叉引用 Cross-referencing

**2.4.1.1 The crossref field (BibTeX)** The crossref field is a convenient way to establish a parent/child relation between two associated entries. Unfortunately, the BibTeX program uses symmetric field mapping which reduces the usefulness of the crossref field significantly. The are two issues with symmetric field mapping, as seen in the following example:

```
@Book{book,
 author
              = {Author},
 bookauthor
              = {Author},
 title
               = {Booktitle},
 booktitle
              = {Booktitle},
 subtitle
               = {Booksubtitle},
 booksubtitle = {Booksubtitle},
 publisher
              = {Publisher},
 location
              = {Location},
 date
              = \{1995\},
}
@InBook{inbook,
 crossref
              = \{book\},
               = {Title},
 title
 subtitle
              = \{ \}
              = \{5--25\},
 pages
}
```

As BibTeX is not capable of mapping the title field of the parent to the booktitle field of the child, the title of the book needs to be given twice. The style then needs to ignore the booktitle of the parent since it is only required to work around this fundamental limitation of BibTeX. The problem with the subtitle field is the inverse of that. Since the subtitle of the parent would become the subtitle, rather than in the booksubtitle, of the child, we need to add an empty subtitle field to the child entry to prevent inheritance of this field. Of course we also need to duplicate the subtitle in the parent entry to ensure that it is available as booksubtitle in the

child entry. In short, using BibTeX's crossref field tends to bloat database files and corrupt the data model.

**2.4.1.2 The crossref field (Biber)** With Biber, the limitations of BibTeX's crossref field belong to the past. Biber features a highly customizable cross-referencing mechanism with flexible data inheritance rules. Duplicating certain fields in the parent entry or adding empty fields to the child entry is no longer required. Entries are specified in a natural way:

```
@Book{book,
  author
                = {Author},
                = {Booktitle},
  title
                = {Booksubtitle},
  subtitle
                = {Publisher},
  publisher
  location
               = {Location},
  date
                = \{1995\},
@InBook{inbook,
  crossref
               = \{book\},
  title
                = {Title},
                = \{5--25\},
  pages
}
```

The title field of the parent will be copied to the booktitle field of the child, the subtitle becomes the booksubtitle. The author of the parent becomes the bookauthor of the child and, since the child does not provide an author field, it is also duplicated as the author of the child. After data inheritance, the child entry is similar to this:

```
author
                 = {Author},
                 = {Author},
bookauthor
title
                 = {Title},
booktitle
                = {Booktitle},
                = {Booksubtitle},
booksubtitle
publisher
                 = {Publisher},
location
                 = {Location},
date
                 = \{1995\},
                 = \{5--25\},
pages
```

See appendix B for a list of mapping rules set up by default. Note that all of this is customizable. See § 4.5.10 on how to configure Biber's cross-referencing mechanism. See also § 2.2.3.

Parameter	Switch	Capacity				
		Default	big	huge	wolfgang	
max_cites	mcites	750	2000	5000	7500	
max_ent_ints	mentints	3000	4000	5000	7500	
max_ent_strs	mentstrs	3000	6000	10000	10000	
max_fields	mfields	17250	30000	85000	125000	
max_strings	mstrings	4000	10000	19000	30000	
pool_size	mpool	65530	130000	500000	750000	
wiz_fn_space	mwizfuns	3000	6000	10000	10000	
hash_prime		4253	8501	16319	30011	
hash_size		5000	10000	19000	35000	

Table 4: Capacity and Switches of bibtex8

2.4.1.3 The xref field In addition to the crossref field, Biblatex supports a simplified cross-referencing mechanism based on the xref field. This is useful if you want to establish a parent/child relation between two associated entries but prefer to keep them independent as far as the data is concerned. The xref field differs from crossref in that the child entry will not inherit any data from the parent. If the parent is referenced by a certain number of child entries, Biblatex will automatically add it to the bibliography. The threshold is controlled by the mincrossrefs package option from § 3.1.2.1. The xref field is supported with all backends. See also § 2.2.3.

## 2.4.2 能力问题 Capacity Issues

**2.4.2.1 BibTeX** 当参考文献量较大时, BibTeX 可能存在内存不足的情形, 这里给出了一些出错情况。最后建议使用 bibtex8 或 biber。

**2.4.2.2 bibtex8** bibtex8 比之 bibtex 有所增强,还有一些参数设置可以增大默认能力。但其能力仍然有限,还可能存在内存不足的问题。

2.4.2.3 Biber Biber 可以消除上述所有局限。

## 2.4.3 排序和编码问题 Sorting and Encoding Issues

**2.4.3.1 BibTeX** Traditional BibTeX can only alphabetize Ascii characters correctly. If the bibliographic data includes non-Ascii characters, they have to be given in Ascii notation. For example, instead of typing a letter like 'ä' directly, you need to input it as \"a, using an accent command and the Ascii letter. This Ascii notation needs to be wrapped in a pair of curly braces. Traditional BibTeX will then ignore the accent and use the Ascii letter for sorting. Here are a few examples:

```
author = {S{\'a}nchez, Jos{\'e}},
editor = {Ma{\ss}mann, R{\"u}diger},
translator = {Ferdi{\'e}re, Fr{\c{c}}ois},
title = {{\OE}uvres compl{\'e}tes},
```

Apart from it being inconvenient, there are two major issues with this convention. One subtle problem is that the extra set of braces suppresses the kerning on both sides of all non-Ascii letters. But first and foremost, simply ignoring all accents may not be the correct way to handle them. For example, in Danish, the letter 'å' is the very last letter of the alphabet, so it should be alphabetized after 'z'. BibTeX will sort it like an 'a'. The 'æ' ligature and the letter 'ø' are also sorted after 'z' in this language. There are similar cases in Norwegian. In Swedish, the letter 'ö' is the very last letter of the alphabet and the letters 'å' and 'ä' are also alphabetized after 'z', rather than like an 'a'. What's more, even the sorting of Ascii characters is done in a rather peculiar way by traditional BibTeX because the sorting algorithm uses Ascii codepage order (0-9, A-Z, a-z). This implies that the lowercase letter 'a' would end up after the uppercase 'Z', which is not even acceptable in the language BibTeX was originally designed for. The traditional bst files work around this problem by converting all strings used for sorting to lowercase, i. e., sorting is effectively case-insensitive. See also § 2.4.3.4.

2.4.3.2 bibtex8 Switching to bibtex8 will help in such cases. bibtex8 can sort case-sensitively and it can handle 8-bit characters properly, provided that you supply it with a suitable csf file and give the --csfile switch on the command line. This also implies that it is possible to apply language specific sorting rules to the bibliography. The Biblatex package comes with csf files for some common Western European encodings. bibtex8 also ships with a few csf files. Note that biblatex.bst can not detect if it is running under traditional BibTeX or bibtex8, hence the bibtex8 package option. By default, sorting is case-insensitive since this is required for traditional BibTeX. If the bibtex8 package option is enabled, sorting is case-sensitive.

Since bibtex8 is backwards compatible with traditional BibTeX, it is possible to mix 8-bit input and Ascii notation. This is useful if the encoding used in the bib file does not cover all required characters. There are also a few marginal cases in which the Ascii notation scheme would yield better sorting results. A typical example is the ligature 'œ'. bibtex8 will handle this ligature like a single character. Depending on the sorting scheme defined in the csf file, it could be treated like an 'o' or alphabetized after the letter 'o' but it can not be sorted as 'oe'. The Ascii notation (\oe) is equivalent to 'oe' during sorting:

```
title = {@uvres complètes},
title = {{\OE}uvres complètes},
```

Sometimes even that is not sufficient and further tricks are required. For example, the letter 'ß' in German is particularly tricky. This letter is essentially alphabetized as 'ss' but after 'ss'. The name 'Baßmann' would be alphabetized as follows: Basmann/Baßmann/Baßmann/Bastmann. In this case, the Ascii notation (\ss) would yield slightly better sorting results than 'ß' in conjunction with a csf file which treats 'ß' like 's':

```
author = {Ba{\ss}mann, Paul},
```

To get it absolutely right, however, you need to resort to the sortname field:

```
author = {Baßmann, Paul},
sortname = {Basszzmann, Paul},
```

Not only BibTeX, LaTeX needs to know about the encoding as well. See § 2.4.3.4 on how to specify encodings.

2.4.3.3 Biber Biber handles Ascii, 8-bit encodings such as Latin 1, and UTF-8. It features true Unicode support and is capable of reencoding the bib data on the fly in a robust way. For sorting, Biber uses a Perl implementation of the Unicode Collation Algorithm (UCA), as outlined in Unicode Technical Standard #10.8 Collation tailoring based on the Unicode Common Locale Data Repository (CLDR) is also supported.9 The bottom line is that Biber will deliver sorting results far superior to both BibTeX and bibtex8 in many cases. If you are interested in the technical details, section 1.8 of Unicode Technical Standard #10 will provide you with a very concise summary of why the inadequateness of traditional BibTeX and even bibtex8 is of a very general nature and not limited to the lack of UTF-8 support.<sup>10</sup>

Supporting Unicode implies much more than handling UTF-8 input. Unicode is a complex standard covering more than its most well-known parts, the Unicode character encoding and transport encodings such as UTF-8. It also standardizes aspects such as string collation, which is required for language-sensitive sorting. For example, by using the Unicode Collation Algorithm, Biber can handle the character 'ß' mentioned as an example in § 2.4.3.2 without any manual intervention. All you need to do to get localized sorting is specify the locale:

```
\usepackage[backend=biber, sortlocale=de] {biblatex}
```

or if you are using german as the main document language via Babel or Polyglossia:

```
\usepackage[backend=biber, sortlocale=auto] {biblatex}
```

This will make Biblatex pass the Babel/Polyglossia main document language as the locale which Biber will map into a suitable default locale. Biber will not try to get locale information from its environment as this makes document processing dependent on something not in the document which is against TeX's spirit of reproducibility. This also makes sense since Babel/Polyglossia are in fact the relevant environment for a document. Note that this will also work with 8-bit encodings such as Latin 9, i. e., you can take advantage of Unicode-based sorting even though you are not using UTF-8 input. See § 2.4.3.4 on how to specify input and data encodings properly.

<sup>8</sup>http://unicode.org/reports/tr10/

<sup>9</sup>http://cldr.unicode.org/

<sup>10</sup>http://unicode.org/reports/tr10/#Common\_Misperceptions

2.4.3.4 Specifying Encodings When using a non-Ascii encoding in the bib file, it is important to understand what Biblatex can do for you and what may require manual intervention. The package takes care of the LaTeX side, i.e., it ensures that the data imported from the bbl file is interpreted correctly, provided that the bibencoding package option is set properly. Depending on the backend, the BibTeX side may demand attention, too. When using bibtex8, you need to supply bibtex8 with a matching csf file as it needs to know about the encoding of the bib file to be able to alphabetize the entries correctly. Unfortunately, there is no way for Biblatex to pass this information to bibtex8 automatically. The only way is setting its --csfile option on the command line when running bibtex8. When using Biber, all of this is handled automatically and no further steps, apart from setting the bibencoding option in certain cases, are required. Here are a few typical usage scenarios along with the relevant lines from the document preamble:

• Ascii notation in both the tex and the bib file with pdfTeX or traditional TeX (this will work with BibTeX, bibtex8, and Biber):

```
\usepackage{biblatex}
```

• Latin 1 encoding (Iso-8859-1) in the tex file, Ascii notation in the bib file with pdfTeX or traditional TeX (BibTeX, bibtex8, Biber):

```
\usepackage[latin1]{inputenc}
\usepackage[bibencoding=ascii]{biblatex}
```

• Latin 9 encoding (ISO-8859-15) in both the tex and the bib file with pdfTeX or traditional TeX (bibtex8, Biber):

```
\usepackage[latin9]{inputenc}
\usepackage[bibencoding=auto]{biblatex}
```

Since bibencoding=auto is the default setting, the option is omissible. The following setup will have the same effect:

```
\usepackage[latin9]{inputenc}
\usepackage{biblatex}
```

• UTF-8 encoding in the tex file, Latin 1 (ISO-8859-1) in the bib file with pdfTeX or traditional TeX (bibtex8, Biber):

```
\usepackage[utf8]{inputenc}
\usepackage[bibencoding=latin1]{biblatex}
```

The same scenario with XeTeX or LuaTeX in native UTF-8 mode:

```
\usepackage[bibencoding=latin1] {biblatex}
```

• Using UTF-8 encoding in both the tex and the bib file is not possible with traditional BibTeX or bibtex8 since neither of them is capable of handling UTF-8. Unless you switch to Biber, you need to use an 8-bit encoding such as Latin 1 (see above) or resort to Ascii notation in this case:

```
\usepackage[utf8]{inputenc}
\usepackage[bibencoding=ascii]{biblatex}
```

The same scenario with XeTeX or LuaTeX in native UTF-8 mode:

```
\usepackage[bibencoding=ascii] {biblatex}
```

Biber can handle Ascii notation, 8-bit encodings such as Latin 1, and UTF-8. It is also capable of reencoding the bib data on the fly (replacing the limited macro-level reencoding feature of Biblatex). This will happen automatically if required, provided that you specify the encoding of the bib files properly. In addition to the scenarios discussed above, Biber can also handle the following cases:

• Transparent UTF-8 workflow, i. e., UTF-8 encoding in both the tex and the bib file with pdfTeX or traditional TeX:

```
\usepackage[utf8]{inputenc}
\usepackage[bibencoding=auto]{biblatex}
```

Since bibencoding=auto is the default setting, the option is omissible:

```
\usepackage[utf8]{inputenc}
\usepackage{biblatex}
```

The same scenario with XeTeX or LuaTeX in native UTF-8 mode:

```
\usepackage{biblatex}
```

• It is even possible to combine an 8-bit encoded tex file with UTF-8 encoding in the bib file, provided that all characters in the bib file are also covered by the selected 8-bit encoding:

```
\usepackage[latin1]{inputenc}
\usepackage[bibencoding=utf8]{biblatex}
```

Some workarounds may be required when using traditional TeX or pdfTeX with UTF-8 encoding because inputenc's utf8 module does not cover all of Unicode. Roughly speaking, it only covers the Western European Unicode range. When loading inputenc with the utf8 option, Biblatex will normally instruct Biber to reencode the bib data to UTF-8. This may lead to inputenc errors if some of the characters in the bib file are outside the limited Unicode range supported by inputenc.

• If you are affected by this problem, try setting the safeinputenc option:

```
\usepackage[utf8]{inputenc}
\usepackage[safeinputenc]{biblatex}
```

If this option is enabled, Biblatex will ignore inputenc's utf8 option and use Ascii. Biber will then try to convert the bib data to Ascii notation. For example, it will convert S. to \k{S}. This option is similar to setting texencoding=ascii but will only take effect in this specific scenario (inputenc/inputenx with UTF-8). This workaround takes advantage of the fact that both Unicode and the UTF-8 transport encoding are backwards compatible with Ascii.

This solution may be acceptable as a workaround if the data in the bib file is mostly Ascii anyway, with only a few strings, such as some authors' names, causing problems. However, keep in mind that it will not magically make traditional TeX or pdfTeX support Unicode. It may help if the occasional odd character is not supported by inputenc, but may still be processed by TeX when using an accent command (e.g., \d{S} instead of \$). If you need full Unicode support, however, switch to XeTeX or LuaTeX.

Typical errors when inputenc cannot handle a certain UTF-8 character are:

Package inputenc Error: Unicode char \u8: not set up for use with LaTeX but also less obvious things like:

! Argument of \UTFviii@three@octets has an extra }.

## 2.4.4 编纂者脚本 Editors and Compiler Scripts

本节需要更新以配合 Biblatex 使用的新的脚本接口。目前,草稿内容可以参考logreq包的说明文档<sup>11</sup>和 Biblatex 开发者百科<sup>12</sup>。

# 3 用户使用手册

本部分介绍 biblatex 包的用户接口。这一部分的用户指南包含了所有要使用标准样式的信息。无论如何首先要阅读这一用户指南,如果要写自己的样式,则需要继续阅读后面的作者指南。

<sup>11</sup>http://www.ctan.org/tex-archive/macros/latex/contrib/logreq/

<sup>12</sup>http://sourceforge.net/apps/mediawiki/biblatex/index.php?title=Workflow\_ Automation

# 3.1 宏包选项

所有的包选项都以〈key〉=〈value〉形式标记。对于所有的布尔选项,其值 true 都可以忽略。比如给出sortcites不带选项值等价于 sortcites=true。

## 3.1.1 加载选项

下面的选项必须在 Biblatex 加载时给出,即作为\usepackage命令的可选参数。

backend=bibtex, bibtex8, bibtexu, biber

default: biber

用于指定数据库后端。支持的后端包括:

biber Biber, Biblatex 的默认后端,支持 Ascii, 8-bit 编码, UTF-8, 再编码<sup>13</sup>, 本地定制排序和很多其他特性。本地定制排序、大小写敏感排序、大小写优先分别由sortlocale, sortcase, 和sortupper选项控制。

bibtex 遗留的 BibTeX. 传统的 BibTeX 仅支持 Ascii 编码。排序总是大小写敏感。

bibtex8,BibTeX的 8-bit 实现,支持 Ascii 和 8-bit 编码比如 Latin 1。 根据csf文件,可以支持大小写敏感排序

bibtexu bibtexu是 BibTeX 为支持 Unicode 的实现版本,可以支持UTF-8。注意 Biblatex 不主动支持bibtexu,并没有以任何方式进行测试。Biber则是推荐的后端。

关于bib文件编码的更多说明见§ 2.4.3节。该选项仅在加载的是偶作为内部选项提供,代码根据 backend 选择完全不同的路径。这意味着不能用导言区的命令比如\ExecuteBibliographyOptions设置后端。

style=\(\file\) default: numeric

加载参考文献著录样式file.bbx 和标注样式file.cbx。各标准样式介绍见§3.3节。

bibstyle=(file) default: numeric

加载参考文献著录样式file.bbx。各标准著录样式介绍见§3.3.2节。

citestyle= $\langle file \rangle$  default: numeric

加载参考文献标注样式file.cbx。各标准标注样式介绍见§3.3.1节。

natbib=true, false default: false

加载兼容模块,提供了natbib包的引用命令的同名替代命令。详见§3.7.9节。

mcite=true, false default: false

加载一个引用命令模块,提供了类似mcite/mciteplus的引用命令。详见 § 3.7.10节。

56

<sup>&</sup>lt;sup>13</sup>on-the-fly?

#### 3.1.2 导言区选项

**3.1.2.1** 一般选项 下面的选项可以作为\usepackage命令的可选参数,也可以在配置文件和导言区设置。默认值列在右侧作为包的默认值。注意著录和标注样式可以修改加载时的默认设置,详见 § 3.3节。

参考文献的排序方式。除非进行声明,否则条目以升序排列。下面提供的是预设可选值:

nty Sort by name, title, year.

nyt Sort by name, year, title.

nyvt Sort by name, year, volume, title.

anyt Sort by alphabetic label, name, year, title.

anyvt Sort by alphabetic label, name, year, volume, title.

ynt Sort by year, name, title.

ydnt Sort by year (descending), name, title.

none Do not sort at all. All entries are processed in citation order.

debug Sort by entry key. This is intended for debugging only.

 $\langle name \rangle$  Use  $\langle name \rangle$ , as defined with \DeclareSortingScheme (§ 4.5.5) Biber only

Using any of the 'alphabetic' sorting schemes only makes sense in conjunction with a bibliography style which prints the corresponding labels. Note that some bibliography styles initialize this package option to a value different from the package default (nty). See § 3.3.2 for details. Please refer to § 3.5 for an in-depth explanation of the above sorting options as well as the fields considered in the sorting process. See also § 4.5.5 on how to adapt the predefined schemes or define new ones.

```
sortcase=true, false default: true
```

Whether or not to sort the bibliography and the list of shorthands case-sensitively. Note that case-sensitive sorting is only supported by the bibtex8 and Biber backends. Sorting is always case-insensitive with legacy BibTeX. See the backend option for details.

```
sortupper=true, false default: true Biber only
```

This option corresponds to Biber's --sortupper command-line option. It has no effect with any other backend. If enabled, the bibliography is sorted in 'uppercase before lowercase' order. Disabling this option means 'lowercase before uppercase' order.

sortlocale=auto,  $\langle locale \rangle$  Biber only

This option sets the global sorting locale. Every sorting scheme inherits this locale if none is specified using the  $\langle locale \rangle$  option to \printbibliography. Setting this to auto requests that it be set to the Babel/Polyglossia main document language identifier, if these packages are used and en\_US otherwise. Biber will map Babel/Polyglossia language identifiers into sensible locale identifiers (see the Biber documentation). You can therefore specify either a normal locale identifier like de\_DE\_phonebook, es\_ES or one of the supported Babel/Polyglossia language identifiers if the mapping Biber makes of this is fine for you.

sortlos=bib, los default: los BibTeX only

The sorting order of the list of shorthands. The following choices are available:

bib Sort according to the sorting order of the bibliography.

los Sort by shorthand.

The sorting order of shorthands with Biber is more flexible and is set with the sorting option to the \printbiblist command.

related=true, false default: true Biber only

Whether or not to use information from related entries or not. See § 3.4.

是否使用相关条目的信息。

sortcites=true, false default: false

Whether or not to sort citations if multiple entry keys are passed to a citation command. If this option is enabled, citations are sorted according to the current bibliography context sorting scheme (see § 3.6.11). This feature works with all citation styles.

当多个条目关键词传给引用命令时,是否进行排序。

 $maxnames = \langle integer \rangle$  default: 3

A threshold affecting all lists of names (author, editor, etc.). If a list exceeds this threshold, i. e., if it holds more than  $\langle integer \rangle$  names, it is automatically truncated according to the setting of the minnames option. maxnames is the master option which sets both maxbibnames and maxcitenames.

最大名字数量,超过截断。

 $minnames = \langle integer \rangle$  default: 1

A limit affecting all lists of names (author, editor, etc.). If a list holds more than  $\langle maxnames \rangle$  names, it is automatically truncated to  $\langle minnames \rangle$  names. The  $\langle minnames \rangle$  value must be smaller than or equal to  $\langle maxnames \rangle$ . minnames is the master option which sets both minbibnames and mincitenames.

超过多于(maxnames)的名字,截断到(minnames) names。

maxbibnames=\(integer\) default: \(\lambda maxnames\rangle\)

Similar to maxnames but affects only the bibliography.

 $minbibnames = \langle integer \rangle$  default:  $\langle minnames \rangle$ 

Similar to minnames but affects only the bibliography.

maxcitenames=\(\langle integer \rangle \) default: \(\langle maxnames \rangle \)

Similar to maxnames but affects only the citations in the document body.

mincitenames=\(\langle integer \rangle \) default: \(\langle minnames \rangle \)

Similar to minnames but affects only the citations in the document body.

maxitems=\(integer\) default: 3

Similar to maxnames, but affecting all literal lists (publisher, location, etc.). 最大项数类似于姓名的处理,用于publisher, location等域。

minitems=\(integer\) default: 1

Similar to minnames, but affecting all literal lists (publisher, location, etc.).

autocite=plain, inline, footnote, superscript, ...

控制引用文字的样式。注意 superscript 选项只有在以数字引用的样式中使用,其它则总是可以。

This option controls the behavior of the \autocite command discussed in § 3.7.4. The plain option makes \autocite behave like \cite, inline makes it behave like \parencite, footnote makes it behave like \footcite, and superscript makes it behave like \supercite. The options plain, inline, and footnote are always available, the superscript option is only provided by the numeric citation styles which come with this package. The citation style may also define additional options. The default setting of this option depends on the selected citation style, see § 3.3.1.

autopunct=true, false default: true

This option controls whether the citation commands scan ahead for punctuation marks. See § 3.7 and \DeclareAutoPunctuation in § 4.7.5 for details.

控制引用命令是否在标点前扫描。

language=autobib, autocite, auto, ⟨language⟩ default: autobib

This option controls multilingual support. When set to autobib, autocite or auto, Biblatex will try to get the main document language from the babel/polyglossia package (and fall back to English if babel/polyglossia is not available). It is also possible to select the document language manually. In this

case, the autolang option below will have no effect. Please refer to table 2 for a list of supported languages and the corresponding identifiers. autobib switches the language for each entry in the bibliography using the language field and the language environment specified by the autolang option. autocite switches the language for each citation using the language field and the language environment specified by the autolang option. auto is a shorthand to set both autobib and autocite. The default is to switch languages automatically only for bibliography entries (autobib).

clearlang=true, false

default: true

If this option is enabled, Biblatex will automatically clear the language field of all entries whose language matches the babel/polyglossia language of the document (or the language specified explicitly with the language option) in order to omit redundant language specifications. The language mappings required by this feature are provided by the \DeclareRedundantLanguages command from § 4.9.1.

autolang=none, hyphen, other, other\*, langname

default: none

This option controls which babel language environment<sup>14</sup> is used if the babel/polyglossia package is loaded and a bibliography entry includes a langid field (see § 2.2.3). Note that Biblatex automatically adjusts to the main document language if babel/polyglossia is loaded. In multilingual documents, it will also continually adjust to the current language as far as citations and the default language of the bibliography is concerned. This option is for switching languages on a per-entry basis within the bibliography. The possible choices are:

none Disable this feature, i. e., do not use any language environment at all.

hyphen Enclose the entry in a hyphenrules environment. This will load hyphenation patterns for the language specified in the hyphenation field of the entry, if available.

Enclose the entry in an otherlanguage environment. This will load hyphenation patterns for the specified language, enable all extra definitions which babel/polyglossia and Biblatex provide for the respective language, and translate key terms such as 'editor' and 'volume'. The extra definitions include localizations of the date format, of ordinals, and similar things.

other\* Enclose the entry in an otherlanguage\* environment. Please note that Biblatex treats otherlanguage\* like otherlanguage but other packages may make a distinction in this case.

langname polyglossia only. Enclose the entry in a 'languagename' environment. The benefit of this option value for polyglossia users

<sup>14</sup>polyglossia understands the babel language environments too and so this option controls both the babel and polyglossia language environments.

is that it takes note of the langidopts field so that you can add perlanguage options to an entry (like selecting a language variant). When using babel, this option does the same as the other option value.

block=none, space, par, nbpar, ragged

default: none

default: foot+end

block= 选项控制块之间的额外空间,比如参考文献条目的更大部分。

This option controls the extra spacing between blocks, i. e., larger segments of a bibliography entry. The possible choices are:

none Do not add anything at all. 不添加任何东西

space Insert additional horizontal space between blocks. This is similar to the default behavior of the standard LaTeX document classes. 在块之间插入水平空间,类似于 latex 文档类的默认方式。

Start a new paragraph for every block. This is similar to the openbib option of the standard LaTeX document classes. 开启新的一段,类似于标准 latex 文档类的openbib选项。

nbpar Similar to the par option, but disallows page breaks at block boundaries and within an entry. 类似域 par选项,但在条目中块边界处不允许分页。

Inserts a small negative penalty to encourage line breaks at block boundaries and sets the bibliography ragged right. 插入一个负的罚值用于鼓励在块的编辑处换行,使其左对齐。

The \newblockpunct command may also be redefined directly to achieve different results, see § 3.9.1. Also see § 4.7.1 for additional information.

\newblockpunct可以重定义实现不同的效果,见§3.9.1。更多的信息参见§4.7.1。

notetype=foot+end, footonly, endonly

该选项控制\mkbibfootnote,\mkbibendnote或类似 § 4.10.4的 wrappers 的行为。

This option controls the behavior of \mkbibfootnote, \mkbibendnote, and similar wrappers from § 4.10.4. The possible choices are:

foot+end Support both footnotes and endnotes, i. e., \mkbibfootnote will generate footnotes and \mkbibendnote will generate endnotes.

脚注和尾注分开

footonly Force footnotes, i. e., make \mkbibendnote generate footnotes. 都生成脚注

endonly Force endnotes, i. e., make \mkbibfootnote generate endnotes. 都生成尾注

default: auto

是否形成超连接,需要样式文件支持。标准样式支持。

Whether or not to transform citations and back references into clickable hyperlinks. This feature requires the hyperref package. It also requires support by the selected citation style. All standard styles which ship with this package support hyperlinks. hyperref=auto automatically detects if the hyperref package has been loaded.

backref=true, false

default: false

是否形成反向超连接,需要样式文件支持。标准样式支持。

Whether or not to print back references in the bibliography. The back references are a list of page numbers indicating the pages on which the respective bibliography entry is cited. If there are refsection environments in the document, the back references are local to the reference sections. Strictly speaking, this option only controls whether the Biblatex package collects the data required to print such references. This feature still has to be supported by the selected bibliography style. All standard styles which ship with this package do so.

backrefstyle=none, three, two, two+, three+, all+

default: three

控制反向连接的页码连续形式。

This option controls how sequences of consecutive pages in the list of back references are formatted. The following styles are available:

none Disable this feature, i. e., do not compress the page list.

Compress any sequence of three or more consecutive pages to a range, e.g., the list '1, 2, 11, 12, 13, 21, 22, 23, 24' is compressed to '1, 2, 11–13, 21–24'.

Compress any sequence of two or more consecutive pages to a range, e. g., the above list is compressed to '1-2, 11-13, 21-24'.

Similar in concept to two but a sequence of exactly two consecutive pages is printed using the starting page and the localization string sequens, e.g., the above list is compressed to '1 sq., 11–13, 21–24'.

three+ Similar in concept to two+ but a sequence of exactly three consecutive pages is printed using the starting page and the localization string sequentes, e.g., the above list is compressed to '1 sq., 11 sqq., 21-24'.

all+ Similar in concept to three+ but any sequence of consecutive pages is printed as an open-ended range, e.g., the above list is compressed to '1 sq., 11 sqq., 21 sqq.'.

All styles support both Arabic and Roman numerals. In order to avoid potentially ambiguous lists, different sets of numerals will not be mixed when generating ranges, e. g., the list 'iii, iv, v, 6, 7, 8' is compressed to 'iii–v, 6–8'.

backrefsetstyle=setonly, memonly, setormem, setandmem, default: setonly

memandset, setplusmem

控制 set 条目如何反向连接。

This option controls how back references to @set entries and their members are handled. The following options are available:

setonly All back references are added to the @set entry. The pageref lists of

set members remain blank.

memonly References to set members are added to the respective member. Refer-

ences to the  $\ensuremath{\operatorname{\mathfrak{gset}}}$  entry are added to all members. The  $\ensuremath{\operatorname{\mathsf{pageref}}}$  list

of the @set entry remains blank.

setormem References to the @set entry are added to the @set entry. References

to set members are added to the respective member.

setandmem References to the @set entry are added to the @set entry. References

to set members are added to the respective member and to the @set

entry.

memandset References to the @set entry are added to the @set entry and to all

members. References to set members are added to the respective mem-

default: false

ber.

setplusmem References to the @set entry are added to the @set entry and to all members. References to set members are added to the respective mem-

ber and to the @set entry.

indexing=true, false, cite, bib

该选项控制在参考文献或引用中使用索引。

This option controls indexing in citations and in the bibliography. More precisely, it affects the \ifciteindex and \ifbibindex commands from § 4.6.2. The option is settable on a global, a per-type, or on a per-entry basis. The possible choices are:

true Enable indexing globally.

false Disable indexing globally.

cite Enable indexing in citations only.

bib Enable indexing in the bibliography only.

This feature requires support by the selected citation style. All standard styles which ship with this package support indexing of both citations and entries in the bibliography. Note that you still need to enable indexing globally with \makeindex to get an index.

```
loadfiles=true, false
```

This option controls whether external files requested by way of the  $\printfile$  command are loaded. See also § 3.11.8 and  $\printfile$  in § 4.4.1. Note that this feature is disabled by default for performance reasons.

refsection=none, part, chapter, section, subsection

default: none

default: false

该选项自动产生一个新的参考文献分部在文档划分为章节的时候。This option automatically starts a new reference section at a document division such as a chapter or a section. This is equivalent to the \newrefsection command, see § 3.6.5 for details. The following choice of document divisions is available:

none Disable this feature.

Start a reference section at every \part command.

chapter Start a reference section at every \chapter command.

section Start a reference section at every \section command.

subsection Start a reference section at every \subsection command.

带星号的文档划分章节命令不产生参考文献部分。

The starred versions of these commands will not start a new reference section.

refsegment=none, part, chapter, section, subsection

default: none

类似于 refsection 选项。

Similar to the refsection option but starts a new reference segment. This is equivalent to the \newrefsegment command, see § 3.6.6 for details. When using both options, note that you can only apply this option to a lower-level document division than the one refsection is applied to and that nested reference segments will be local to the enclosing reference section.

citereset=none, part, chapter, section, subsection

default: none

该选项控制在文档划分时自动执行\citereset 命令。

This option automatically executes the \citereset command from § 3.7.8 at a document division such as a chapter or a section. The following choice of document divisions is available:

none Disable this feature.

part Perform a reset at every \part command.

chapter Perform a reset at every \chapter command.

section Perform a reset at every \section command.

subsection Perform a reset at every \subsection command.

The starred versions of these commands will not trigger a reset.

default: true

是否在引用和参考文献中使用长或缩略的字符串。

Whether or not to use long or abbreviated strings in citations and in the bibliography. This option affects the localization modules. If this option is enabled, key terms such as 'editor' are abbreviated. If not, they are written out.

date=year, short, long, terse, comp, iso8601

default: comp

该选项控制打印日期的规范。

This option controls the basic format of printed date specifications. The following choices are available:

year Use only years, for example:

2010

2010-2012

short Use the short format with verbose ranges, for example:

01/01/2010

21/01/2010-30/01/2010

01/21/2010-01/30/2010

long Use the long format with verbose ranges, for example:

1st January 2010

21st January 2010-30th January 2010

January 21, 2010-January 30, 2010

terse Use the short format with compact ranges, for example:

21-30/01/2010

01/21-01/30/2010

Comp Use the long format with compact ranges, for example:

21st-30th January 2010

January 21-30, 2010

iso8601 Use extended iso-8601 format (yyyy-mm-dd), for example:

2010-01-01

2010-01-21/2010-01-30

As seen in the above examples, the actual date format is language specific. Note that the month name in all long formats is responsive to the abbreviate package option. The leading zeros in all short formats may be controlled separately with the datezeros package option.

datelabel=year, short, long, terse, comp, iso8601

default: year

类似域 date 选项,但控制由\DeclareLabeldate命令选择的日期域。

Similar to the date option but controls the format of the date field selected with \DeclareLabeldate.

origdate=year, short, long, terse, comp, iso8601

default: comp

Similar to the date option but controls the format of the origidate.

eventdate=year, short, long, terse, comp, iso8601

default: comp

Similar to the date option but controls the format of the eventdate.

urldate=year, short, long, terse, comp, iso8601

default: short

Similar to the date option but controls the format of the urldate.

alldates=year, short, long, terse, comp, iso8601

设置上述所有的日期选项为相同值。Sets all of the above date options to the same value.

datezeros=true, false

default: true

This option controls whether short and terse dates are printed with leading zeros.

dateabbrev=true, false

default: true

This option controls whether long and comp dates are printed with long or abbreviated month names. The option is similar to the generic abbreviate option but specific to the date formatting.

defernumbers=true, false

default: false

In contrast to standard LaTeX, the numeric labels generated by this package are normally assigned to the full list of references at the beginning of the document body. If this option is enabled, numeric labels (i. e., the labelnumber field discussed in § 4.2.4) are assigned the first time an entry is printed in any bibliography. See § 3.12.5 for further explanation. This option requires two LaTeX runs after the data has been exported to the bbl file by the backend (in addition to any other runs required by page breaks changing etc.). An important thing to note is that if you change the value of this option in your document (or the value of options which depend on this like some of the options to the \printbibliography macro, see § 3.6.2), then it is likely that you will need to delete your current aux file and re-run LaTeX to obtain the correct numbering. See § 4.1.

punctfont=true, false

default: false

启用处理单位标点时的替换机制 This option enables an alternative mechanism for dealing with unit punctuation after a field printed in a different font (for example, a title printed in italics). See \setpunctfont in § 4.7.1 for details.

arxiv=abs, ps, pdf, format

default: abs

Path selector for arXiv links. If hyperlink support is enabled, this option controls which version of the document the arXiv eprint links will point to. The following choices are available:

abs Link to the abstract page.

ps Link to the PostScript version.

pdf Link to the PDF version.

format Link to the format selector page.

See § 3.11.7 for details on support for arXiv and electronic publishing information.

## texencoding=auto, \( \text{encoding} \)

default: auto

指定 tex 文件的编码。

Specifies the encoding of the tex file. This option affects the data transferred from the backend to Biblatex. When using Biber, this corresponds to Biber's --output\_encoding option. The following choices are available:

auto Try to auto-detect the input encoding. If the inputenc/inputenx/

luainputenc package is available, Biblatex will get the main encoding from that package. If not, it assumes UTF-8 encoding if XeTeX or

LuaTeX has been detected, and Ascii otherwise.

 $\langle encoding \rangle$  Specifies the  $\langle encoding \rangle$  explicitly. This is for odd cases in which auto-

detection fails or you want to force a certain encoding for some reason.

Note that setting texencoding= $\langle encoding \rangle$  will also affect the bibencoding option if bibencoding=auto.

#### bibencoding=auto, \( \text{encoding} \)

default: auto

default: false

Biber only

Specifies the encoding of the bib files. When using Biber, this corresponds to Biber's ——input encoding option. The following choices are available:

auto Use this option if the workflow is transparent, i. e., if the encoding of the

bib file is identical to the encoding of the tex file.

(*encoding*) If the encoding of the bib file is different from the one of the tex file,

you need to specify it explicitly.

By default, Biblatex assumes that the tex file and the bib file use the same encoding (bibencoding=auto). Note that some backends only support a limited number of encodings. See § 2.4.3 for further instructions.

## safeinputenc=true, false

If this option is enabled, Biblatex will automatically force texencoding=ascii if the inputenc/inputenx package has been loaded and the input encoding is UTF-8,

i. e., it will ignore any macro-based UTF-8 support and use Ascii only. Biber will then try to convert any non-Ascii data in the bib file to Ascii. For example, it will convert \$ to \d{\$}. See § 2.4.3.4 for an explanation of why you may want to enable this option.

bibwarn=true, false

default: true

By default, Biblatex will report warnings issued by the backend concerning the data in the bib file as LaTeX warnings. Use this option to suppress such warnings.

mincrossrefs=\langle integer \rangle

default: 2

Sets the minimum number of cross references to  $\langle integer \rangle$  when requesting a backend run. Note that when using the BibTeX backend, this package option merely affects the format of certain requests written to the transcript file. It will not have any effect if the editor or compiler script launching BibTeX does not include dedicated Biblatex support or if BibTeX is manually launched from the command-line. See § 2.4.4 for details. This option also affects the handling of the xref field. See the field description in § 2.2.3 as well as § 2.4.1 for details.

**3.1.2.2 Style-specific** The following options are provided by the standard styles (as opposed to the core package). Technically, they are preamble options like those in § 3.1.2.1.

下面的选项是标准样式提供的。技术上来说,它们是导言区选项。

isbn=true, false

default: true

控制类似 isbn 的域是否打印。

This option controls whether the fields isbn/issn/isrn are printed.

url=true, false

default: true

控制 url 域和访问日期是否打印。

This option controls whether the url field and the access date is printed. The option only affects entry types whose url information is optional. The url field of @online entries is always printed.

doi=true, false

default: true

This option controls whether the field doi is printed.

控制 doi 域是否打印

eprint=true, false

default: true

This option controls whether eprint information is printed.

控制 eprint 信息是否打印。

<sup>15</sup> If an entry which is cross-referenced by other entries in the bib file hits this threshold, it is included in the bibliography even if it has not been cited explicitly. This is a standard feature of the BibTeX (also Biber) and not specific to Biblatex. See the description of the crossref field in § 2.2.3 for further information.

<sup>&</sup>lt;sup>16</sup>As of this writing, no LaTeX editors or compiler scripts with dedicated Biblatex support are known, but this will hopefully change in the future.

**3.1.2.3 Internal** The default settings of the following preamble options are controlled by bibliography and citation styles. Apart from the pagetracker and firstinits options, which you may want to adapt, there is normally no need to set them explicitly.

下面的导言区选项是由样式文件控制的。

pagetracker=true, false, page, spread

default: false

This option controls the page tracker which is required by the \ifsamepage and \iffirstonpage tests from § 4.6.2. The possible choices are:

页码追踪器选项。

Enable the tracker in automatic mode. This is like spread if LaTeX is in twoside mode, and like page otherwise.

false Disable the tracker.

page Enable the tracker in page mode. In this mode, tracking works on a per-

page basis.

spread Enable the tracker in spread mode. In this mode, tracking works on a

per-spread (double page) basis.

Note that this tracker is disabled in all floats, see § 4.11.5.

citecounter=true, false, context

default: false

控制引用计数器的使用模式。

This option controls the citation counter which is required by citecounter from § 4.6.2. The possible choices are:

true Enable the citation counter in global mode.

false Disable the citation counter.

context Enable the citation counter in context-sensitive mode. In this mode, ci-

tations in footnotes and in the body text are counted independently.

citetracker=true, false, context, strict, constrict

default: false

控制引用追踪器的使用模式。

This option controls the citation tracker which is required by the \ifciteseen and \ifentryseen tests from § 4.6.2. The possible choices are:

true Enable the tracker in global mode.

false Disable the tracker.

context Enable the tracker in context-sensitive mode. In this mode, citations in

footnotes and in the body text are tracked independently.

Enable the tracker in strict mode. In this mode, an item is only considered by the tracker if it appeared in a stand-alone citation, i. e., if a single entry key was passed to the citation command.

constrict This mode combines the features of context and strict.

Note that this tracker is disabled in all floats, see § 4.11.5.

控制出处追踪器的使用模式。

This option controls the 'ibidem' tracker which is required by the \ifciteibid test from § 4.6.2. The possible choices are:

true Enable the tracker in global mode.

false Disable the tracker.

context Enable the tracker in context-sensitive mode. In this mode, citations in footnotes and in the body text are tracked separately.

Enable the tracker in strict mode. In this mode, potentially ambiguous references are suppressed. A reference is considered ambiguous if either the current citation (the one including the 'ibidem') or the previous citation (the one the 'ibidem' refers to) consists of a list of references.<sup>17</sup>

constrict This mode combines the features of context and strict. It also keeps track of footnote numbers and detects potentially ambiguous references in footnotes in a stricter way than the strict option. In addition to the conditions imposed by the strict option, a reference in a footnote will only be considered as unambiguous if the current citation and the previous citation are given in the same footnote or in immediately consecutive footnotes.

Note that this tracker is disabled in all floats, see § 4.11.5.

opcittracker=true, false, context, strict, constrict default: false

前述引用追踪器的使用模式。

This option controls the 'opcit' tracker which is required by the \ifopcit test from § 4.6.2. This feature is similar to the 'ibidem' tracker, except that it tracks citations on a per-author/editor basis, i. e., \ifopcit will yield true if the cited item is the same as the last one by this author/editor. The possible choices are:

true Enable the tracker in global mode.

false Disable the tracker.

<sup>&</sup>lt;sup>17</sup>For example, suppose the initial citation is "Jones, *Title*; Williams, *Title*" and the following one "ibidem". From a technical point of view, it is fairly clear that the 'ibidem' refers to 'Williams' because this is the last reference processed by the previous citation command. To a human reader, however, this may not be obvious because the 'ibidem' may also refer to both titles. The strict mode avoids such ambiguous references.

Enable the tracker in context-sensitive mode. In this mode, citations in context footnotes and in the body text are tracked separately.

Enable the tracker in strict mode. In this mode, potentially ambiguous strict references are suppressed. See ibidtracker=strict for details.

This mode combines the features of context and strict. See the constrict

explanation of ibidtracker=constrict for details.

Note that this tracker is disabled in all floats, see § 4.11.5.

loccittracker=true, false, context, strict, constrict default: false

引用位置追踪器。

This option controls the 'loccit' tracker which is required by the \ifloccit test from § 4.6.2. This feature is similar to the 'opcit' tracker except that it also checks whether the *(postnote)* arguments match, i. e., \ifloccit will yield true if the citation refers to the same page cited before. The possible choices are:

true Enable the tracker in global mode.

Disable the tracker. false

Enable the tracker in context-sensitive mode. In this mode, citations in context footnotes and in the body text are tracked separately.

Enable the tracker in strict mode. In this mode, potentially ambiguous strict references are suppressed. See ibidtracker=strict for details. In addition to that, this mode also checks if the *(postnote)* argument is numerical (based on \ifnumerals from § 4.6.2).

constrict This mode combines the features of context and strict. See the explanation of ibidtracker=constrict for details. In addition to that, this mode also checks if the (postnote) argument is numerical (based on  $\vee$  if numerals from § 4.6.2).

Note that this tracker is disabled in all floats, see § 4.11.5.

idemtracker=true, false, context, strict, constrict default: false

同前追踪器。

This option controls the 'idem' tracker which is required by the \ifciteidem test from § 4.6.2. The possible choices are:

Enable the tracker in global mode. true

Disable the tracker. false

Enable the tracker in context-sensitive mode. In this mode, citations in context footnotes and in the body text are tracked separately.

This is an alias for true, provided only for consistency with the other trackers. Since 'idem' replacements do not get ambiguous in the same way as 'ibidem' or 'op. cit.', the strict tracking mode does not apply to them.

constrict This mode is similar to context with one additional condition: a reference in a footnote will only be considered as unambiguous if the current citation and the previous citation are given in the same footnote or in immediately consecutive footnotes.

Note that this tracker is disabled in all floats, see § 4.11.5.

parentracker=true, false

default: true

圆括号追踪器。

This option controls the parenthesis tracker which keeps track of nested parentheses and brackets. This information is used by \parentext and \brackettext from § 3.7.5, \mkbibparens and \mkbibbrackets from § 4.10.4 and \bibopenparen, \bibcloseparen, \bibcloseparen, \bibcloseparen, \bibclosebracket, \bibclosebracket (also § 4.10.4).

 $maxparens = \langle integer \rangle$ 

default: 3

括号嵌套的最大层级。

The maximum permitted nesting level of parentheses and brackets. If parentheses and brackets are nested deeper than this value, Biblatex will issue errors.

firstinits=true, false

default: false

启用名字由首字母表示。

When enabled, all first and middle names will be rendered as initials. The option will affect the \iffirstinits test from § 4.6.2.

sortfirstinits=true, false

default: false

default: false

姓名排序时,利用首字母进行。

When enabled, sorting names will only use their initials. This is separate from firstinits in case users want to show only inits but sort on full names, for example.

Biber only

terseinits=true, false

控制 biblatex 生成的首字母的格式。biber 后端可以重定义一些宏来控制格式,详见 § 3.12.4。

This option controls the format of initials generated by Biblatex. If enabled, initials are rendered using a terse format without dots and spaces. For example, the initials of Donald Ervin Knuth would be rendered as 'D. E.' by default, and as 'DE' if this option

is enabled. The option will affect the \ifterseinits test from § 4.6.2. With Biber, the option works by redefining some macros which control the format of initials. See § 3.12.4 for details.

labelalpha=true, false

default: false

是否提供特殊的域,详见§4.2.4。

Whether or not to provide the special fields labelalpha and extraalpha, see § 4.2.4 for details. With Biber, this option is also settable on a per-type basis. See also maxalphanames and minalphanames. Table 5 summarises the various extra\* disambiguation counters and what they track.

Biber only

Biber only

maxalphanames=\(integer\)

default: 3 Biber only

Similar to the maxnames option but customizes the format of the labelalpha field.

 $minalphanames=\langle integer \rangle$ 

default: 1 Biber only

Similar to the minnames option but customizes the format of the labelalpha field.

labelnumber=true, false

default: false

是否提供特殊域labelnumber。Whether or not to provide the special field labelnumber, see § 4.2.4 for details. This option is also settable on a per-type basis.

labeltitle=true, false

default: false

Biber only

Biber only

是否提供特殊域extratitle。Whether or not to provide the special field extratitle, see § 4.2.4 for details. Note that the special field labeltitle is always provided and this option controls rather whether labeltitle is used to generate extratitle information. This option is also settable on a per-type basis. Table 5 summarises the various extra\* disambiguation counters and what they track.

labeltitleyear=true, false

default: false Biber only

Whether or not to provide the special field extratitleyear, see § 4.2.4 for details. Note that the special field labeltitle is always provided and this option controls rather whether labeltitle is used to generate extratitleyear information. This option is also settable on a per-type basis. Table 5 summarises the various extra\* disambiguation counters and what they track.

labeldate=true, false

default: false

Whether or not to provide the special fields labelyear, labelmonth, labelday and extrayear, see § 4.2.4 for details. With Biber, this option is also settable on a per-type basis. Table 5 summarises the various extra\* disambiguation counters and what they track.

73

```
singletitle=true, false
```

Whether or not to provide the data required by the \ifsingletitle test, see § 4.6.2 for details. With Biber, this option is also settable on a per-type basis.

Biber only

default: false

default: false

Biber only

uniquename=true, false, init, full, allinit, allfull, mininit, default: false Biber only minfull

是否更新uniquename计数器。

Whether or not to update the uniquename counter, see § 4.6.2 for details. This feature will disambiguate individual names in the labelname list. This option is also settable on a per-type basis. The possible choices are:

true	An alias for full.
false	Disable this feature.
init	Disambiguate names using initials only.
full	Disambiguate names using initials or full names, as required.
allinit	Similar to init but disambiguates all names in the labelname list, beyond maxnames/minnames/uniquelist.
allfull	Similar to full but disambiguates all names in the labelname list, beyond maxnames/minnames/uniquelist.
mininit	A variant of init which only disambiguates names in lists with identical last names.
minfull	A variant of full which only disambiguates names in lists with identical last names.

Note that the uniquename option will also affect uniquelist, the \ifsingletitle test, and the extrayear field. See § 4.11.4 for further details and practical examples.

uniquelist=true, false, minyear

是否更新uniquelist计数器。

Whether or not to update the uniquelist counter, see § 4.6.2 for details. This feature will disambiguate the labelname list if it has become ambiguous after maxnames/minnames truncation. Essentially, it overrides maxnames/minnames on a per-field basis. This option is also settable on a per-type basis. The possible choices are:

true Disambiguate the labelname list.

false Disable this feature.

minyear Disambiguate the labelname list only if the truncated list is identical to another one with the same labelyear. This mode of operation is useful for author-year styles and requires labeldate=true.

Option	Enabled field	Enabled counter	Counter tracks
labelalpha	labelalpha	extraalpha	label
labeldate	labelyear	extrayear	labelname+labelyear
labeltitle	-	extratitle	labelname+labeltitle
labeltitleyear	_	extratitleyear	labeltitle+labelyear

**Table 5: Disambiguation counters** 

Note that the uniquelist option will also affect the \ifsingletitle test and the extrayear field. See § 4.11.4 for further details and practical examples.

# 3.1.3 条目选项 Entry Options

Entry options are package options which determine how bibliography data entries are handled. They may be set at various scopes defined below.

条目选项是控制参考文献数据条目处理的包选项。

**3.1.3.1 Preamble/Type/Entry Options** The following options are settable on a pertype basis or on a per-entry in the options field. In addition to that, they may also be used in the optional argument to \usepackage as well as in the configuration file and the document preamble. This is useful if you want to change the default behaviour globally.

下面的选项是可以根据条目和类型重设的。而且也可以在 \usepackage命令中作为选项使用。如果需要改变默认的全局行为会非常有用。

useauthor=true, false

default: true

是否在标签中使用author 或者在排序中考虑。

Whether the author is used in labels and considered during sorting. This may be useful if an entry includes an author field but is usually not cited by author for some reason. Setting useauthor=false does not mean that the author is ignored completely. It means that the author is not used in labels and ignored during sorting. The entry will then be alphabetized by editor or title. With the standard styles, the author is printed after the title in this case. See also § 3.5. With Biber, this option is also settable on a per-type and per-entry basis.

Biber only

useeditor=true, false

default: true

是否用editor代替缺失的author。

Whether the editor replaces a missing author in labels and during sorting. This may be useful if an entry includes an editor field but is usually not cited by editor. Setting useeditor=false does not mean that the editor is ignored completely. It means that the editor does not replace a missing author in labels and during sorting. The entry will then be alphabetized by title. With the standard styles, the editor is printed after the title in this case. See also § 3.5. With Biber, this option is

Biber only

also settable on a per-type and per-entry basis.

```
usetranslator=true, false
```

Whether the translator replaces a missing author/editor in labels and during sorting. Setting usetranslator=true does not mean that the translator overrides the author/editor. It means that the translator is considered as a fallback if the author/editor is missing or if useauthor and useeditor are set to false. In other words, in order to cite a book by translator rather than by author, you need to set the following options: With Biber, this option is also settable on a per-type and per-entry basis.

Biber only

```
@Book{...,
  options = {useauthor=false,usetranslator=true},
  author = {...},
  translator = {...},
```

With the standard styles, the translator is printed after the title by default. See also § 3.5.

```
use<name>=true, false
```

default: true

default: false

As per useauthor, useeditor and usetranslator, all name lists defined in the data model have an option controlling their behaviour in sorting and labelling automatically defined. Global, per-type and per-entry options called 'use<name>'are automatically created.

```
useprefix=true, false
```

default: false

Whether the name prefix (von, van, of, da, de, della, etc.) is considered when printing the last name in citations. This also affects the sorting and formatting of the bibliography as well as the generation of certain types of labels. If this option is enabled, Biblatex always precedes the last name with the prefix. For example, Ludwig van Beethoven would be cited as "Beethoven" and alphabetized as "Beethoven, Ludwig van" by default. If this option is enabled, he is cited as "van Beethoven" and alphabetized as "Van Beethoven, Ludwig" instead. With Biber, this option is also settable on a per-type basis.

Biber only

```
indexing=true, false, cite, bib
```

The indexing option is also settable per-type or per-entry basis. See § 3.1.2.1 for details.

**3.1.3.2 Type/Entry Options** The following options are settable on a per-type basis or on a per-entry in the options field. They are not available globally.

skipbib=true, false

If this option is enabled, the entry is excluded from the bibliography but it may still be cited. With Biber, this option is also settable on a per-type basis.

Biber only

BibTeX only

Biber only

Biber only

Biber only

default: false

default: false

default: false

default: false

default: false

skiplos=true, false

If this option is enabled, the entry is excluded from the list of shorthands. It is still included in the bibliography and it may also be cited by shorthand. This option is deprecated when using Biber as the backend. Use skipbiblist instead.

skipbiblist=true, false

This is the same as the skiplos option when using the BibTeX backend. It is renamed for Biber to be consistent with the more generalised bibliography list functionality See § 3.6.4. If this option is enabled, the entry is excluded from the list of shorthands. It is still included in the bibliography and it may also be cited by shorthand. This option is also settable on a per-type basis.

skiplab=true, false

If this option is enabled, Biblatex will not assign any labels to the entry. It is not required for normal operation. Use it with care. If enabled, Biblatex can not guarantee unique citations for the respective entry and citations styles which require labels may fail to create valid citations for the entry. With Biber, this option is also settable on a per-type basis.

dataonly=true, false

Setting this option is equivalent to uniquename=false, uniquelist=false, skipbib, skiplos/skipbiblist, and skiplab. It is not required for normal operation. Use it with care. With Biber, this option is also settable on a per-type basis.

**3.1.3.3 Entry Only Options** The following options are settable only on a per-entry in the options field. They are not available globally or per-type.

labelnamefield=\( fieldname \)

Specifies the field to consider first when looking for a labelname candidate. It is essentially prepended to the search list created by \DeclareLabelname for just this entry.

labeltitlefield=\langle fieldname\rangle

Specifies the field to consider first when looking for a labeltitle candidate. It is essentially prepended to the search list created by \DeclareLabeltitle for just this entry.

### 3.1.4 遗留选项 Legacy Options

下面的遗留选项可以在\documentclass中全局使用或者在\usepackage中作为可选参数。

openbib 这一选项用于兼容标准的 LaTeX 文档类。openbib类似于 block=par。

Deprecated

## 3.2 全局定制 Global Customization

除了写新的标注和参考文献样式,还有多种方式来定制本宏包提供的样式。定制可以在导言区中进行,也可以在配置文件中进行以便长期使用。配置文件也用来初始化与默认值不同的包选项。

### 3.2.1 配置文件 Configuration File

如果提供该文件,则包将加载该配置文件biblatex.cfg。该文件在包末尾读入, 紧跟在标注和参考文献样式后面。

## 3.2.2 设置包选项 Setting Package Options

§ 3.1.1节的加载用包选项必须在\usepackage的可选参数中给出。§ 3.1.2给出的包选项也需要在导言区给出。这些选项与如下命令一起使用:

\ExecuteBibliographyOptions [ $\langle entrytype, ... \rangle$ ] { $\langle key=value, ... \rangle$ }

This command may also be used in the configuration file to modify the default setting of a package option. Certain options are also settable on a per-type basis. In this case, the optional  $\langle entrytype \rangle$  argument specifies the entry type. The  $\langle entrytype \rangle$  argument may be a comma-separated list of values.

## 3.3 标准样式 Standard Styles

This section provides a short description of all bibliography and citation styles which ship with the Biblatex package. If you want to write your own styles, see § 4.

# 3.3.1 标注样式 Citation Styles

The citation styles which come with this package implement several common citation schemes. All standard styles cater for the shorthand field and support hyperlinks as well as indexing.

numeric This style implements a numeric citation scheme similar to the standard bibliographic facilities of LaTeX. It should be employed in conjunction with a numeric bibliography style which prints the corresponding labels in the bibliography. It is intended for in-text citations. The style will set the following package options at load time: autocite=inline, labelnumber=true. This style also provides an additional preamble option called subentry which affects the handling of entry sets. If this option is disabled, citations referring to a member of a set will point to the entire set. If it is enabled,

the style supports citations like "[5c]" which point to a subentry in a set (the third one in this example). See the style example for details.

numeric-comp

A compact variant of the numeric style which prints a list of more than two consecutive numbers as a range. This style is similar to the cite package and the sort&compress option of the natbib package in numerical mode. For example, instead of "[8, 3, 1, 7, 2]" this style would print "[1-3, 7, 8]". It is intended for in-text citations. The style will set the following package options at load time: autocite=inline, sortcites=true, labelnumber=true. It also provides the subentry option.

numeric-verb

A verbose variant of the numeric style. The difference affects the handling of a list of citations and is only apparent when multiple entry keys are passed to a single citation command. For example, instead of "[2, 5, 6]" this style would print "[2]; [5]; [6]". It is intended for in-text citations. The style will set the following package options at load time: autocite=inline, labelnumber=true. It also provides the subentry option.

alphabetic

This style implements an alphabetic citation scheme similar to the alpha.bst style of traditional BibTeX. The alphabetic labels resemble a compact author-year style to some extent, but the way they are employed is similar to a numeric citation scheme. For example, instead of "Jones 1995" this style would use the label "[Jon95]". "Jones and Williams 1986" would be rendered as "[JW86]". This style should be employed in conjunction with an alphabetic bibliography style which prints the corresponding labels in the bibliography. It is intended for in-text citations. The style will set the following package options at load time: autocite=inline, labelalpha=true.

alphabetic-verb

A verbose variant of the alphabetic style. The difference affects the handling of a list of citations and is only apparent when multiple entry keys are passed to a single citation command. For example, instead of "[Doe92; Doe95; Jon98]" this style would print "[Doe92]; [Doe95]; [Jon98]". It is intended for in-text citations. The style will set the following package options at load time: autocite=inline, labelalpha=true.

authoryear

This style implements an author-year citation scheme. If the bibliography contains two or more works by the same author which were all published in the same year, a letter is appended to the year. For example, this style would print citations such as "Doe 1995a; Doe 1995b; Jones 1998". This style should be employed in conjunction with an author-year bibliography style which prints the corresponding labels in the bibliography. It is primarily intended for in-text citations, but it could also be used with citations given in footnotes. The style will set the following package options at load time: autocite=inline, labeldate=true, uniquename=full, uniquelist=true.

authoryear-comp

A compact variant of the authoryear style which prints the author only once if subsequent references passed to a single citation command share the same author. If they

share the same year as well, the year is also printed only once. For example, instead of "Doe 1995b; Doe 1992; Jones 1998; Doe 1995a" this style would print "Doe 1992, 1995a,b; Jones 1998". It is primarily intended for in-text citations, but it could also be used with citations given in footnotes. The style will set the following package options at load time: autocite=inline, sortcites=true, labeldate=true, uniquename=full, uniquelist=true.

authoryear-ibid

A variant of the authoryear style which replaces repeated citations by the abbreviation ibidem unless the citation is the first one on the current page or doublepage spread, or the ibidem would be ambiguous in the sense of the package option ibidtracker = constrict. The style will set the following package options at load time: autocite = inline, labeldate = true, uniquename = full, uniquelist=true, ibidtracker=constrict, pagetracker=true. This style also provides an additional preamble option called ibidpage. See the style example for details.

authoryear-icomp

A style combining authoryear-comp and authoryear-ibid. The style will set the following package options at load time: autocite=inline, labeldate= true, uniquename=full, uniquelist=true, ibidtracker=constrict, pagetracker=true, sortcites=true. This style also provides an additional preamble option called ibidpage. See the style example for details.

authortitle This style implements a simple author-title citation scheme. It will make use of the shorttitle field, if available. It is intended for citations given in footnotes. The style will set the following package options at load time: autocite=footnote, uniquename=full, uniquelist=true.

authortitle-comp

A compact variant of the authortitle style which prints the author only once if subsequent references passed to a single citation command share the same author. For example, instead of "Doe, First title; Doe, Second title" this style would print "Doe, First title, Second title". It is intended for citations given in footnotes. The style will set the following package options at load time: autocite=footnote, sortcites= true, uniquename=full, uniquelist=true.

authortitle-ibid

A variant of the authortitle style which replaces repeated citations by the abbreviation *ibidem* unless the citation is the first one on the current page or double-page spread, or the *ibidem* would be ambiguous in the sense of the package option ibidtracker= constrict. It is intended for citations given in footnotes. The style will set the following package options at load time: autocite=footnote, uniquename=full, uniquelist=true, ibidtracker=constrict, pagetracker=true. This style also provides an additional preamble option called ibidpage. See the style example for details.

authortitle-icomp

A style combining the features of authortitle-comp and authortitle-ibid. The style will set the following package options at load time: autocite=footnote, uniquename = full, uniquelist = true, ibidtracker = constrict, pagetracker=true, sortcites=true. This style also provides an additional preamble option called ibidpage. See the style example for details.

authortitle-terse

A terse variant of the authortitle style which only prints the title if the bibliography contains more than one work by the respective author/editor. This style will make use of the shorttitle field, if available. It is suitable for in-text citations as well as citations given in footnotes. The style will set the following package options at load time: autocite=inline, singletitle=true, uniquename=full, uniquelist=true.

authortitle-tcomp

A style combining the features of authortitle-comp and authortitle-terse. This style will make use of the shorttitle field, if available. It is suitable for in-text citations as well as citations given in footnotes. The style will set the following package options at load time: autocite=inline, sortcites=true, singletitle=true, uniquename=full, uniquelist=true.

authortitle-ticomp

A style combining the features of authortitle-icomp and authortitle-terse. In other words: a variant of the authortitle-tcomp style with an *ibidem* feature. This style is suitable for in-text citations as well as citations given in footnotes. It will set the following package options at load time: autocite = inline, ibidtracker = constrict, pagetracker = true, sortcites=true, singletitle=true, uniquename=full, uniquelist=true. This style also provides an additional preamble option called ibidpage. See the style example for details.

verbose

A verbose citation style which prints a full citation similar to a bibliography entry when an entry is cited for the first time, and a short citation afterwards. If available, the shorttitle field is used in all short citations. If the shorthand field is defined, the shorthand is introduced on the first citation and used as the short citation thereafter. This style may be used without a list of references and shorthands since all bibliographic data is provided on the first citation. It is intended for citations given in footnotes. The style will set the following package options at load time: autocite=footnote, citetracker=context. This style also provides an additional preamble option called citepages. See the style example for details.

verbose-ibid

A variant of the verbose style which replaces repeated citations by the abbreviation *ibidem* unless the citation is the first one on the current page or double-page spread, or the *ibidem* would be ambiguous in the sense of <code>ibidtracker=strict</code>. This style is intended for citations given in footnotes. The style will set the following package options at load time: <code>autocite=footnote</code>, <code>citetracker=context</code>, <code>ibidtracker=constrict</code>, <code>pagetracker=true</code>. This style also provides additional preamble options called <code>ibidpage</code> and <code>citepages</code>. See the style example for details.

verbose-note

This style is similar to the verbose style in that it prints a full citation similar to a bibliography entry when an entry is cited for the first time, and a short citation afterwards. In contrast to the verbose style, the short citation is a pointer to the footnote with the full citation. If the bibliography contains more than one work by the respective author/editor, the pointer also includes the title. If available, the shorttitle field is used in all short citations. If the shorthand field is defined, it is handled as with the verbose style. This style may be used without a list of references and shorthands since all bibliographic data is provided on the first citation. It is exclusively intended for citations given in footnotes. The style will set the following package options at load time: autocite=footnote, citetracker=context, singletitle=true. This style also provides additional preamble options called pageref and citepages. See the style example for details.

verbose-inote

A variant of the verbose-note style which replaces repeated citations by the abbreviation *ibidem* unless the citation is the first one on the current page or double-page spread, or the *ibidem* would be ambiguous in the sense of <code>ibidtracker=strict</code>. This style is exclusively intended for citations given in footnotes. It will set the following package options at load time: <code>autocite=footnote</code>, <code>citetracker=context</code>, <code>ibidtracker=constrict</code>, <code>singletitle=true</code>, <code>pagetracker=true</code>. This style also provides additional preamble options called <code>ibidpage</code>, <code>pageref</code>, and <code>citepages</code>. See the style example for details.

verbose-trad1

This style implements a traditional citation scheme. It is similar to the verbose style in that it prints a full citation similar to a bibliography entry when an item is cited for the first time, and a short citation afterwards. Apart from that, it uses the scholarly abbreviations *ibidem*, *idem*, *op. cit.*, and *loc. cit.* to replace recurrent authors, titles, and page numbers in repeated citations in a special way. If the shorthand field is defined, the shorthand is introduced on the first citation and used as the short citation thereafter. This style may be used without a list of references and shorthands since all bibliographic data is provided on the first citation. It is intended for citations given in footnotes. The style will set the following package options at load time: autocite = footnote, citetracker = context, ibidtracker = constrict, idemtracker = constrict, opcittracker = context, loccittracker = context. This style also provides additional preamble options called ibidpage, strict, and citepages. See the style example for details.

verbose-trad2

Another traditional citation scheme. It is also similar to the verbose style but uses scholarly abbreviations like *ibidem* and *idem* in repeated citations. In contrast to the verbose-trad1 style, the logic of the *op. cit.* abbreviations is different in this style and *loc. cit.* is not used at all. It is in fact more similar to verbose-ibid and verbose-inote than to verbose-trad1. The style will set the following package options at load time: autocite=footnote, citetracker=context, ibidtracker=constrict, idemtracker=constrict. This style also pro-

vides additional preamble options called ibidpage, strict, and citepages. See the style example for details.

verbose-trad3 Yet another traditional citation scheme. It is similar to the verbose-trad2 style but uses the scholarly abbreviations *ibidem* and *op. cit.* in a slightly different way. The style will set the following package options at load time: autocite=footnote, citetracker = context, ibidtracker = constrict, loccittracker = constrict. This style also provides additional preamble options called strict and citepages. See the style example for details.

reading A citation style which goes with the bibliography style by the same name. It simply loads the authortitle style.

The following citation styles are special purpose styles. They are not intended for the final version of a document:

draft A draft style which uses the entry keys in citations. The style will set the following package options at load time: autocite=plain.

debug This style prints the entry key rather than some kind of label. It is intended for debugging only and will set the following package options at load time: autocite=plain.

## 3.3.2 参考文献样式 Bibliography Styles

All bibliography styles which come with this package use the same basic format for the individual bibliography entries. They only differ in the kind of label printed in the bibliography and the overall formatting of the list of references. There is a matching bibliography style for every citation style. Note that some bibliography styles are not mentioned below because they simply load a more generic style. For example, the bibliography style authortitle-comp will load the authortitle style.

numeric This style prints a numeric label similar to the standard bibliographic facilities of LaTeX. It is intended for use in conjunction with a numeric citation style. Note that the shorthand field overrides the default label. The style will set the following package options at load time: labelnumber=true. This style also provides an additional preamble option called subentry which affects the formatting of entry sets. If this option is enabled, all members of a set are marked with a letter which may be used in citations referring to a set member rather than the entire set. See the style example for details.

alphabetic This style prints an alphabetic label similar to the alpha.bst style of traditional BibTeX. It is intended for use in conjunction with an alphabetic citation style. Note that the shorthand field overrides the default label. The style will set the following package options at load time: labelalpha=true, sorting=anyt.

authoryear This style differs from the other styles in that the publication date is not printed towards the end of the entry but rather after the author/editor. It is intended for use in conjunction with an author-year citation style. Recurring author and editor names are replaced by a dash unless the entry is the first one on the current page or double-page spread. This style provides an additional preamble option called dashed which controls this feature. It also provided a preamble option called mergedate. See the style example for details. The style will set the following package options at load time: labeldate=true, sorting=nyt, pagetracker=true, mergedate=true.

authortitle This style does not print any label at all. It is intended for use in conjunction with an author-title citation style. Recurring author and editor names are replaced by a dash unless the entry is the first one on the current page or double-page spread. This style also provides an additional preamble option called dashed which controls this feature. See the style example for details. The style will set the following package options at load time: pagetracker=true.

verbose This style is similar to the authortitle style. It also provides an additional preamble option called dashed. See the style example for details. The style will set the following package options at load time: pagetracker=true.

This special bibliography style is designed for personal reading lists, annotated bibliographies, and similar applications. It optionally includes the fields annotation, abstract, library, and file in the bibliography. If desired, it also adds various kinds of short headers to the bibliography. This style also provides the additional preamble options entryhead, entrykey, annotation, abstract, library, and file which control whether or not the corresponding items are printed in the bibliography. See the style example for details. See also § 3.11.8. The style will set the following package options at load time: loadfiles=true, entryhead=true, entrykey=true, annotation=true, abstract=true, library=true, file=true.

The following bibliography styles are special purpose styles. They are not intended for the final version of a document:

draft This draft style includes the entry keys in the bibliography. The bibliography will be sorted by entry key. The style will set the following package options at load time: sorting=debug.

debug This style prints all bibliographic data in tabular format. It is intended for debugging only and will set the following package options at load time: sorting=debug.

## 3.4 相关条目 Related Entries

Almost all bibliography styles require authors to specify certain types of relationship between entries such as "Reprint of", "Reprinted in" etc. It is impossible to provide data fields to cover all of these relationships and so Biblatex provides a general mechanism for this using the entry fields related, relatedtype and relatedstring. A related entry does not need to be cited and does not appear in the bibliography itself (unless of course it is also cited itself independently) as a clone is taken of the related entry to be used as a data source. The relatedtype field should specify a localization string which will be printed before the information from the related entries is printed, for example "Orig. Pub. as". The relatedstring field can be used to override the string determined via relatedtype. Some examples:

```
@Book{key1,
    ...
    related = {key2},
    relatedtype = {reprintof},
    ...
}
@Book{key2,
    ...
}
```

Here we specify that entry key1 is a reprint of entry key2. In the bibliography driver for Book entries, when \usebibmacro{related} is called for entry key1:

- If the localization string "reprintof" is defined, it is printed in the relatedstring:reprintof format. If this formatting directive is undefined, the string is printed in the relatedstring:default format.
- If the related:reprintof macro is defined, it is used to format the information contained in entry key2, otherwise the related:default macro is used
- If the related: reprintof format is defined, it is used to format both the localization string and data. If this format is not defined, then the related format is used instead.

It is also supported to have cascading and/or circular relations:

```
@Book{key1,
    ...
    related = {key2},
    relatedtype = {reprintof},
    ...
}
@Book{key2,
    ...
```

```
related = {key3},
  relatedtype = {translationof},
  ...
}

@Book{key3,
  ...
  related = {key2},
  relatedtype = {translatedas},
  ...
}
```

Multiple relations to the same entry are also possible:

```
@MVBook{key1,
    ...
    related = {key2, key3},
    relatedtype = {multivolume},
    ...
}

@Book{key2,
    ...
}
@Book{key3,
    ...
}
```

Note the order of the keys in lists of multiple related entries is important. The data from multiple related entries is printed in the order of the keys listed in this field. See § 4.5.1 for a more details on the mechanisms behind this feature. You can turn this feature off using the package option related from § 3.1.2.1.

You can use the relatedoptions to set options on the related entry data clone. This is useful if you need to override the dataonly option which is set by default on all related entry clones. For example, if you will expose some of the names in the related clone in your document, you may want to have them disambiguated from names in other entries but normally this won't happen as related clones have the per-entry dataonly option set and this in turn sets uniquename = false and uniquelist=false. In such a case, you can set relatedoptions to just skiplab, skipbib, skiplos/skipbiblist.

# 3.5 排序选项 Sorting Options

This package supports various sorting schemes for the bibliography. The sorting scheme is selected with the sorting package option from § 3.1.2.1. Apart from the regular data fields there are also some special fields which may be used to optimize the sorting of the bibliography. Appendices C.1 and C.2 give an outline of the alphabetic sorting schemes supported by Biblatex. Chronological sorting schemes are listed in appendix C.3. A few explanations concerning these schemes are in order.

The first item considered in the sorting process is always the presort field of the entry. If this field is undefined, Biblatex will use the default value 'mm' as a presort string. The next item considered is the sortkey field. If this field is defined, it serves as the master sort key. Apart from the presort field, no further data is considered in this case. If the sortkey field is undefined, sorting continues with the name. The package will try using the sortname, author, editor, and translator fields, in this order. Which fields are considered also depends on the setting of the use<name> options. If all such options are disabled, the sortname field is ignored as well. Note that all name fields are responsive to maxnames and minnames. If no name field is available, either because all of them are undefined or because all use<name> options are disabled, Biblatex will fall back to the sorttitle and title fields as a last resort. The remaining items are, in various order: the sortyear field, if defined, or the first four digits of the year field otherwise; the sorttitle field, if defined, or the title field otherwise; the volume field, which is padded to four digits with leading zeros, or the string 0000 otherwise. Note that the sorting schemes shown in appendix C.2 include an additional item: labelalpha is the label used by 'alphabetic' bibliography styles. Strictly speaking, the string used for sorting is labelalpha + extraalpha. The sorting schemes in appendix C.2 are intended to be used in conjunction with alphabetic styles only.

The chronological sorting schemes presented in appendix C.3 also make use of the presort and sortkey fields, if defined. The next item considered is the sortyear or the year field, depending on availability. The ynt scheme extracts the first four Arabic figures from the field. If both fields are undefined, the string 9999 is used as a fallback value. This means that all entries without a year will be moved to the end of the list. The ydnt scheme is similar in concept but sorts the year in descending order. As with the ynt scheme, the string 9999 is used as a fallback value. The remaining items are similar to the alphabetic sorting schemes discussed above. Note that the ydnt sorting scheme will only sort the date in descending order. All other items are sorted in ascending order as usual.

Using special fields such as sortkey, sortname, or sorttitle is usually not required. The Biblatex package is quite capable of working out the desired sorting order by using the data found in the regular fields of an entry. You will only need them if you want to manually modify the sorting order of the bibliography or if any data required for sorting is missing. Please refer to the field descriptions in § 2.2.3 for details on

possible uses of the special fields. Also note that using Biber instead of legacy BibTeX is strongly recommended.

# 3.6 参考文献命令 Bibliography Commands

### 3.6.1 文献数据源 Resources

\addbibresource[\langle options \rangle] \{ \langle resource \rangle \rangle resource \rangle resource \rangle \rangle resource \rangle \rangle resource \rangle

Adds a  $\langle resource \rangle$ , such as a .bib file, to the default resource list. This command is only available in the preamble. It replaces the \bibliography legacy command. Note that files must be specified with their full name, including the extension. Do not omit the .bib extension from the filename. Also note that the  $\langle resource \rangle$  is a single resource. Invoke \addbibresource multiple times to add more resources, for example:

```
\addbibresource{bibfile1.bib}
\addbibresource{bibfile2.bib}
\addbibresource[location=remote] {http://www.citeulike.org/bibtex/group/9517}
\addbibresource[location=remote,label=lan] {ftp://192.168.1.57/~user/file.bib
```

Since the  $\langle resource \rangle$  string is read in a verbatim-like mode, it may contain arbitrary characters. The only restriction is that any curly braces must be balanced. The following  $\langle options \rangle$  are available:

```
label=(identifier)
```

Assigns a label to a resource. The  $\langle identifier \rangle$  may be used in place of the full resource name in the optional argument of refsection (see § 3.6.5).

```
location=\langle location \rangle default: local
```

The location of the resource. The  $\langle location \rangle$  may be either local for local resources or remote for urls. Remote resources require Biber. The protocols http and ftp are supported. The remote url must be a fully qualified path to a bib file or a url which returns a bib file.

```
type=\langle type \rangle default: file
```

The type of resource. Currently, the only supported type is file.

```
datatype = \langle datatype \rangle default: bibtex
```

The data type (format) of the resource. The following formats are currently supported:

bibtex	BibTeX format.	
ris	Research Information Systems (RIS) format. $^{18}$ Note that an ID tag	Biber only
	is required in all RIS records. The ${\tt ID}$ value corresponds to the entry	
	key. Support for this format is experimental.	
zoterordfxml	Zotero RDF/XML format. Support for this format is experimental.	Biber only
	Refer to the Biber manual for details.	

<sup>18</sup>http://en.wikipedia.org/wiki/RIS\_(file\_format)

endnotexml EndNote xml format. Support for this format is experimental. Re-Biber only fer to the Biber manual for details.

```
\addglobalbib[\langle options \rangle] \{\langle resource \rangle\}
```

This command differs from \addbibresource in that the  $\langle resource \rangle$  is added to the global resource list. The difference between default resources and global resources is only relevant if there are reference sections in the document and the optional argument of refsection (§ 3.6.5) is used to specify alternative resources which replace the default resource list. Any global resources are added to all reference sections.

```
\addsectionbib[\langle options \rangle] \{\langle resource \rangle\}
```

This command differs from \addbibresource in that the resource  $\langle options \rangle$  are registered but the  $\langle resource \rangle$  not added to any resource list. This is only required for resources which 1) are given exclusively in the optional argument of refsection (§ 3.6.5) and 2) require options different from the default settings. In this case, \addsectionbib is employed to qualify the  $\langle resource \rangle$  prior to using it by setting the appropriate  $\langle options \rangle$  in the preamble. The label option may be useful to assign a short name to the resource.

```
\bibliography{\langle bibfile, ... \rangle}
```

Deprecated

The legacy command for adding bibliographic resources, supported for backwards compatibility. Like \addbibresource, this command is only available in the preamble and adds resources to the default resource list. Its argument is a comma-separated list of bib files. The .bib extension may be omitted from the filename. Invoking this command multiple times to add more files is permissible. This command is deprecated. Please consider using \addbibresource instead.

## 3.6.2 参考文献表 The Bibliography

```
\printbibliography[\langle key=value, ... \rangle]
```

This command prints the bibliography. It takes one optional argument, which is a list of options given in  $\langle key \rangle = \langle value \rangle$  notation. The following options are available:

```
env=(name) default: bibliography/shorthands
```

The 'high-level' layout of the bibliography and the list of shorthands is controlled by environments defined with  $\defbibenvironment$ . This option selects an environment. The  $\langle name \rangle$  corresponds to the identifier used when defining the environment with  $\defbibenvironment$ . By default, the  $\printbibliography$  command uses the identifier bibliography;  $\printbiblist$  uses shorthands. See also §§ 3.6.4 and 3.6.8.

The bibliography and the list of shorthands typically have a chapter or section heading. This option selects the heading  $\langle name \rangle$ , as defined with \defbibheading. By default, the \printbibliography command uses the heading bibliography; \printbiblist uses shorthands. See also §§ 3.6.4 and 3.6.8.

```
title=\langle text \rangle
```

This option overrides the default title provided by the heading selected with the heading option, if supported by the heading definition. See § 3.6.8 for details.

```
prenote=(name)
```

The prenote is an arbitrary piece of text to be printed after the heading but before the list of references. This option selects the prenote  $\langle name \rangle$ , as defined with \defbibnote. By default, no prenote is printed. The note is printed in the standard text font. It is not affected by \bibsetup and \bibfont but it may contain its own font declarations. See § 3.6.9 for details.

```
postnote=(name)
```

The postnote is an arbitrary piece of text to be printed after the list of references. This option selects the postnote  $\langle name \rangle$ , as defined with \defbibnote. By default, no postnote is printed. The note is printed in the standard text font. It is not affected by \bibsetup and \bibfont but it may contain its own font declarations. See § 3.6.9 for details.

```
section=⟨integer⟩ default: current section
```

Print only entries cited in reference section  $\langle integer \rangle$ . The reference sections are numbered starting at 1. All citations given outside a refsection environment are assigned to section 0. See § 3.6.5 for details and § 3.11.3 for usage examples.

```
segment=\(integer\) default: 0
```

Print only entries cited in reference segment  $\langle integer \rangle$ . The reference segments are numbered starting at 1. All citations given outside a refsegment environment are assigned to segment 0. See § 3.6.6 for details and § 3.11.3 for usage examples. Remember that segments within a section are numbered local to the section so the segment you request will be the nth segment in the requested (or currently active enclosing) section.

```
type=\(entrytype\)
```

Print only entries whose entry type is  $\langle entrytype \rangle$ .

```
nottype=\(\rho entrytype\)
```

Print only entries whose entry type is not  $\langle entrytype \rangle$ . This option may be used multiple times.

```
subtype = \langle subtype \rangle
```

Print only entries whose entry subtype is defined and (*subtype*).

```
notsubtype=\(\langle subtype \rangle \)
```

Print only entries whose entry subtype is undefined or not  $\langle subtype \rangle$ . This option may be used multiple times.

```
keyword=\langle keyword \rangle
```

Print only entries whose keywords field includes  $\langle keyword \rangle$ . This option may be used multiple times.

```
notkeyword=\langle keyword \rangle
```

Print only entries whose keywords field does not include  $\langle keyword \rangle$ . This option may be used multiple times.

```
category=\(category\)
```

Print only entries assigned to category  $\langle category \rangle$ . This option may be used multiple times.

```
notcategory=\(category\)
```

Print only entries not assigned to category  $\langle category \rangle$ . This option may be used multiple times.

```
filter=\langle name \rangle
```

Filter the entries with filter  $\langle name \rangle$ , as defined with \defbibfilter. See § 3.6.10 for details.

```
check=\langle name \rangle
```

Filter the entries with check  $\langle name \rangle$ , as defined with \defbibcheck. See § 3.6.10 for details.

```
prefixnumbers=\langle string\rangle
```

This option applies to numerical citation/bibliography styles only and requires that the defernumbers option from § 3.1.2.1 be enabled globally. Setting this option will implicitly enable resetnumbers for the current bibliography. The option assigns the  $\langle string \rangle$  as a prefix to all entries in the respective bibliography. For example, if the  $\langle string \rangle$  is A, the numerical labels printed will be [A1], [A2], [A3], etc. This is useful for subdivided numerical bibliographies where each subbibliography uses a different prefix. The  $\langle string \rangle$  is available to styles in the prefixnumber field of all affected entries. See § 4.2.4.2 for details.

```
resetnumbers=\langle true, false, number\rangle
```

This option applies to numerical citation/bibliography styles only and requires that the defernumbers option from § 3.1.2.1 be enabled globally. If enabled, it will reset the numerical labels assigned to the entries in the respective bibliography, i. e., the numbering will restart at 1. You can also pass a number to this option, for example: resetnumbers=10 to reset numbering to the specified number to aid numbering continuity across documents. Use this option with care as Biblatex can not guarantee unique labels globally if they are reset manually.

```
omitnumbers=true, false
```

This option applies to numerical citation/bibliography styles only and requires that the defernumbers option from § 3.1.2.1 be enabled globally. If enabled, Biblatex will not assign a numerical label to the entries in the respective bibliography. This is useful when mixing a numerical subbibliography with one or more subbibliographies using a different scheme (e.g., author-title or author-year).

```
\bibbysection[\langle key=value, ... \rangle]
```

This command automatically loops over all reference sections. This is equivalent to giving one \printbibliography command for every section but has the additional benefit of automatically skipping sections without references. Note that \bibbysection starts looking for references in section 1. It will ignore references given outside of refsection environments since they are assigned to section 0. See § 3.11.3 for usage examples. The options are a subset of those supported by \printbibliography. Valid options are env, heading, prenote, postnote. The current bibliography context sorting scheme is used for all sections (see § 3.6.11).

```
\bibbysegment[\langle key=value, ... \rangle]
```

This command automatically loops over all reference segments. This is equivalent to giving one \printbibliography command for every segment in the current refsection but has the additional benefit of automatically skipping segments without references. Note that \bibbysegment starts looking for references in segment 1. It will ignore references given outside of refsegment environments since they are assigned to segment 0. See § 3.11.3 for usage examples. The options are a subset of those supported by \printbibliography. Valid options are env, heading, prenote, postnote. The current bibliography context sorting scheme is used for all segments (see § 3.6.11).

### \bibbycategory [ $\langle key=value, ... \rangle$ ]

This command loops over all bibliography categories. This is equivalent to giving one \printbibliography command for every category but has the additional benefit of automatically skipping empty categories. The categories are processed in the order in which they were declared. See § 3.11.3 for usage examples. The options are a subset

of those supported by \printbibliography. Valid options are env, prenote, postnote, section. Note that heading is not available with this command. The name of the current category is automatically used as the heading name. This is equivalent to passing heading=\(\care category\)\to \printbibliography and implies that there must be a matching heading definition for every category. The current bibliography context sorting scheme is used for all categories (see § 3.6.11).

### \printbibheading[ $\langle key=value, ... \rangle$ ]

This command prints a bibliography heading defined with  $\defbibheading$ . It takes one optional argument, which is a list of options given in  $\langle key \rangle = \langle value \rangle$  notation. The options are a small subset of those supported by  $\printbibliography$ . Valid options are heading and title. By default, this command uses the heading bibliography. See § 3.6.8 for details. Also see §§ 3.11.3 and 3.11.4 for usage examples.

To print a bibliography with a different sorting scheme than the global sorting scheme, use the bibliography context switching commands from § 3.6.11.

### 3.6.3 缩略表 The List of Shorthands

This section applies only to BibTeX. When using Biber, the list of shorthands is just a BibTeX only special case of a bibliography list. See § 3.6.4.<sup>19</sup>

If any entry includes a shorthand field, biblatex automatically builds a list of shorthands which may be printed in addition to the regular bibliography. The following command prints the list of shorthands.

### \printshorthands [ $\langle key=value, ... \rangle$ ]

This command prints the list of shorthands. It takes one optional argument, which is a list of options given in  $\langle key \rangle = \langle value \rangle$  notation. Valid options are all options supported by \printbibliography (§ 3.6.2) except prefixnumbers, resetnumbers, and omitnumbers. If there are any refsection environments in the document, the list of shorthands will be local to these environments; see § 3.6.5 for details. By default, this command uses the heading shorthands. See § 3.6.8 for details.

The sorting option differs from \printbibliography in that if omitted, the default is to sort by shorthand.

## 3.6.4 各类参考文献表 Bibliography Lists

This section applies only to Biber. It is a generalisation of the shorthands facility available in earlier versions and with BibTeX. When using BibTeX as the backend, please refer to section § 3.6.3.

<sup>19</sup>本节需要重点关注一下,之前没有搞清楚

Biblatex can, in addition to printing normal bibliographies, also print arbitrary lists of information derived from the bibliography data such as a list of shorthand abbreviations for particular entries or a list of abbreviations of journal titles.

A bibliography list differs from a normal bibliography in that the same bibliography driver is used to print all entries rather than a specific driver being used for each entry depending on the entry type.

```
\printbiblist[\langle key=value, ... \rangle] \{\langle < biblistname > \rangle\}
```

This command prints a bibliography list. It takes an optional argument, which is a list of options given in  $\langle key \rangle = \langle value \rangle$  notation. Valid options are all options supported by \printbibliography (§ 3.6.2) except prefixnumbers, resetnumbers, and omitnumbers. If there are any refsection environments in the document, the bibliography list will be local to these environments; see § 3.6.5 for details. By default, this command uses the heading biblist. See § 3.6.8 for details.

The  $\langle biblistname \rangle$  is a mandatory argument which names the bibliography list. This name is used to identify:

- •The default bibliography driver used to print the list entries
- •A default filter declared with \DeclareBiblistFilter (see § 4.5.6) used to filter the entries returned from Biber
- •A default check declared with \defbibcheck (see § 3.6.10) used to post-process the list entries
- •The default bib environment to use
- •The default sorting scheme name to use

In terms of sorting the list, the default is to sort use the sorting scheme named after the bibliography list (if it exists) and only then to fall back to the current context sorting scheme is this is not defined (see § 3.6.11).

The most common bibliography list is a list of shorthand abbreviations for certain entries and so this has a convenience alias \printshorthands[...] for backwards compatibility which is defined as:

```
\printbiblist[...] {shorthand}
```

Biblatex provides automatic support for data source fields in the default data model marked as 'Label fields' (See § 2.2.2). Such fields automatically have defined for them:

- •A default bib environment (See § 3.6.8)
- •A bibliography list filter (See § 4.5.6)
- •Some supporting formats and lengths (See § 4.10.5 and § 4.10.4)

Therefore only a minimal setup is required to print bibliography lists with such fields. For example, to print a list of journal title abbreviations, you can minimally put this in your preamble:

```
\DeclareBibliographyDriver{shortjournal}{%
  \printfield{journaltitle}}
```

Then you can put this in your document where you want to print the list:

```
\printbiblist[title={Journal Shorthands}]{shortjournal}
```

Since shortjournal is defined in the default data model as a 'Label field', this example:

- •Uses the automatically created 'shortjournal' bib environment
- •Uses the automatically created 'shortjournal' bibliography list filter to return only entries with a shortjournal field in the .bbl
- •Uses the defined 'shortjournal' bibliography driver to print the entries
- •Uses the default 'biblist' heading but overrides the title with 'Journal Shorthands'
- •Uses the current bibliography context sorting scheme no scheme exists with the name shortjournal

Often, you will want to sort on the label field of the list and since a sorting scheme is automatically picked up if it is named after the list, in this case you could simply do:

```
\DeclareSortingScheme{shortjournal}{
   \sort{
      \field{shortjournal}
   }
}
```

Naturally all defaults can be overridden by options to \printbiblist and definitions of the environments, filters etc. and in this way arbitrary types of bibliography lists can be printed containing a variety of information from the bibliography data.

Bibliography lists are often used to print lists of various kinds of shorthands and this can result in duplicate entries if more than one bibliography entry has the same shorthand. For example, several journal articles in the same journal would result in duplicate entries in a list of journal shorthands. You can use the fact that such lists automatically pick up a <code>\bibcheck</code> with the same name as the list to define a check to remove duplicates. If you are defining a list to print all of the journal shorthands using the <code>shortjournal</code> field, you could define a <code>\bibcheck</code> like this:

```
\defbibcheck{shortjournal}{%
  \iffieldundef{shortjournal}{\skipentry}{%
  \iffieldundef{journal}{\skipentry}{%
  \ifcsdef{\strfield{shortjournal}=\strfield{journal}}}
  {\skipentry}
  {\savefieldcs{journal}{\strfield{shortjournal}=\strfield{journal}}}}}}}
```

95

## 3.6.5 参考文献分节 Bibliography Sections

The refsection environment is used in the document body to mark a reference section. This environment is useful if you want separate, independent bibliographies and bibliography lists in each chapter, section, or any other part of a document. Within a reference section, all cited works are assigned labels which are local to the environment. Technically, reference sections are completely independent from document divisions such as \chapter and \section even though they will most likely be used per chapter or section. See the refsection package option in § 3.1.2.1 for a way to automate this. Also see § 3.11.3 for usage examples.

```
\begin{refsection} [\langle resource, ... \rangle] \end{refsection}
```

The optional argument is a comma-separated list of resources specific to the reference section. If the argument is omitted, the reference section will use the default resource list, as specified with \addbibresource in the preamble. If the argument is provided, it replaces the default resource list. Global resources specified with \addglobalbib are always considered. refsection environments may not be nested, but you may use refsegment environments within a refsection to subdivide it into segments. Use the section option of \printbibliography to select a section when printing the bibliography, and the corresponding option of \printbiblist when printing bibliography lists. Bibliography sections are numbered starting at 1. The number of the current section is also written to the transcript file. All citations given outside a refsection environment are assigned to section 0. If \printbibliography is used within a refsection, it will automatically select the current section. The section option is not required in this case. This also applies to \printbiblist.

```
\newrefsection[\langle resource, ... \rangle]
```

This command is similar to the refsection environment except that it is a standalone command rather than an environment. It automatically ends the previous reference section (if any) and immediately starts a new one. Note that the reference section started by the last \newrefsection command in the document will extend to the very end of the document. Use \endrefsection if you want to terminate it earlier.

## 3.6.6 参考文献分部 Bibliography Segments

The refsegment environment is used in the document body to mark a reference segment. This environment is useful if you want one global bibliography which is subdivided by chapter, section, or any other part of the document. Technically, reference segments are completely independent from document divisions such as \chapter and \section even though they will typically be used per chapter or section. See the refsegment package option in § 3.1.2.1 for a way to automate this. Also see § 3.11.3 for usage examples.

### \begin{refsegment}

#### \end{refsegment}

The difference between a refsection and a refsegment environment is that the former creates labels which are local to the environment whereas the latter provides a target for the segment filter of \printbibliography without affecting the labels. They will be unique across the entire document. refsegment environments may not be nested, but you may use them in conjunction with refsection to subdivide a reference section into segments. In this case, the segments are local to the enclosing refsection environment. Use the segment option of \printbibliography to select a segment when printing the bibliography. Within a section, the reference segments are numbered starting at 1 and the number of the current segment will be written to the transcript file. All citations given outside a refsegment environment are assigned to segment 0. In contrast to the refsection environment, the current segment is not selected automatically if \printbibliography is used within a refsegment environment.

\newrefsegment This command is similar to the refsegment environment except that it is a standalone command rather than an environment. It automatically ends the previous reference segment (if any) and immediately starts a new one. Note that the reference segment started by the last \newrefseqment command will extend to the end of the document. Use \endrefsegment if you want to terminate it earlier.

## 3.6.7 参考文献分类 Bibliography Categories

Bibliography categories allow you to split the bibliography into multiple parts dedicated to different topics or different types of references, for example primary and secondary sources. See § 3.11.4 for usage examples.

```
\DeclareBibliographyCategory{\langle category\rangle}
```

Declares a new \(\langle category \rangle \), to be used in conjunction with \addtocategory and the category and notcategory filters of \printbibliography. This command is used in the document preamble.

```
\addtocategory \{ \langle category \rangle \} \{ \langle key \rangle \}
```

Assigns a  $\langle key \rangle$  to a  $\langle category \rangle$ , to be used in conjunction with the category and notcategory filters of \printbibliography. This command may be used in the preamble and in the document body. The  $\langle key \rangle$  may be a single entry key or a comma-separated list of keys. The assignment is global.

# 3.6.8 参考文献标题和环境 Bibliography Headings and Environments

```
\defbibenvironment\{\langle name \rangle\} \{\langle begin code \rangle\} \{\langle end code \rangle\} \{\langle item code \rangle\}
```

This command defines bibliography environments. The  $\langle name \rangle$  is an identifier passed to the env option of \printbibliography and \printbiblist when selecting the environment. The  $\langle begin\ code \rangle$  is LaTeX code to be executed at the beginning of the environment; the  $\langle end\ code \rangle$  is executed at the end of the environment; the  $\langle item\ code \rangle$  is code to be executed at the beginning of each entry in the bibliography or a bibliography list. Here is an example of a definition based on the standard LaTeX list environment:

```
\defbibenvironment{bibliography}
    {\list{}
        {\setlength{\leftmargin}{\bibhang}%
        \setlength{\itemindent}{-\leftmargin}%
        \setlength{\itemsep}{\bibitemsep}%
        \setlength{\parsep}{\bibparsep}}}
        {\endlist}
        {\item}
```

As seen in the above example, usage of \defbibenvironment is roughly similar to \newenvironment except that there is an additional mandatory argument for the \(\lambda item code\rangle\).

```
\def bibheading \{\langle name \rangle\} [\langle title \rangle] \{\langle code \rangle\}
```

This command defines bibliography headings. The  $\langle name \rangle$  is an identifier to be passed to the heading option of \printbibliography or \printbibheading and \printbiblist when selecting the heading. The  $\langle code \rangle$  should be LaTeX code generating a fully-fledged heading, including page headers and an entry in the table of contents, if desired. If \printbibliography or \printbiblist are invoked with a title option, the title will be passed to the heading definition as #1. If not, the default title specified by the optional  $\langle title \rangle$  argument is passed as #1 instead. The  $\langle title \rangle$  argument will typically be \bibname, \refname, or \biblistname (see § 4.9.2.1). This command is often needed after changes to document headers in the preamble. Here is an example of a simple heading definition:

```
\defbibheading{bibliography} [\bibname] {%
  \chapter*{#1}%
  \markboth{#1}{#1}}
```

The following headings, which are intended for use with \printbibliography and \printbibheading, are predefined:

### bibliography

This is the default heading used by \printbibliography if the heading option is not given. Its default definition depends on the document class. If the class provides a \chapter command, the heading is similar to the bibliography heading of the

standard LaTeX book class, i.e., it uses \chapter\* to create an unnumbered chapter heading which is not included in the table of contents. If there is no \chapter command, it is similar to the bibliography heading of the standard LaTeX article class, i.e., it uses \section\* to create an unnumbered section heading which is not included in the table of contents. The string used in the heading also depends on the document class. With book-like classes the localization string bibliography is used, with other classes it is references (see § 4.9.2). See also §§ 3.12.1 and 3.12.2 for class-specific hints.

#### subbibliography

Similar to bibliography but one sectioning level lower. This heading definition uses \section\* instead of \chapter\* with a book-like class and \subsection\* instead of \section\* otherwise.

#### bibintoc

Similar to bibliography above but adds an entry to the table of contents.

#### subbibintoc

Similar to subbibliography above but adds an entry to the table of contents.

#### bibnumbered

Similar to bibliography above but uses \chapter or \section to create a numbered heading which is also added to the table of contents.

#### subbibnumbered

Similar to subbibliography above but uses \section or \subsection to create a numbered heading which is also added to the table of contents.

#### none

A blank heading definition. Use this to suppress the heading.

The following headings intended for use with \printbiblist are predefined:

### biblist

This is the default heading used by \printbiblist if the heading option is not given. It is similar to bibliography above except that it uses the localization string shorthands instead of bibliography or references (see § 4.9.2). See also §§ 3.12.1 and 3.12.2 for class-specific hints.

### biblistintoc

Similar to biblist above but adds an entry to the table of contents.

#### biblistnumbered

Similar to biblist above but uses \chapter or \section to create a numbered heading which is also added to the table of contents.

# 3.6.9 参考文献注释 Bibliography Notes

```
\defbibnote{\langle name \rangle} {\langle text \rangle}
```

Defines the bibliography note  $\langle name \rangle$ , to be used via the prenote and postnote options of \printbibliography and \printbiblist. The  $\langle text \rangle$  may be any arbitrary piece of text, possibly spanning several paragraphs and containing font declarations. Also see § 3.12.6.

## 3.6.10 参考文献过滤和检查 Bibliography Filters and Checks

```
\defbibfilter{\langle name \rangle} {\langle expression \rangle}
```

Defines the custom bibliography filter  $\langle name \rangle$ , to be used via the filter option of \printbibliography. The  $\langle expression \rangle$  is a complex test based on the logical operators and, or, not, the group separator (...), and the following atomic tests:

```
segment=\(integer\)
```

Matches all entries cited in reference segment *(integer)*.

```
type=\(entrytype\)
```

Matches all entries whose entry type is  $\langle entrytype \rangle$ .

```
subtype=\langle subtype\rangle
```

Matches all entries whose entrysubtype is  $\langle subtype \rangle$ .

```
keyword=\langle keyword \rangle
```

Matches all entries whose keywords field includes  $\langle keyword \rangle$ . If the  $\langle keyword \rangle$  contains spaces, it needs to be wrapped in braces.

```
category=\(category\)
```

Matches all entries assigned to *(category)* with *\addtocategory*.

Here is an example of a filter expression:

```
\defbibfilter{example}{%
  ( type=book or type=inbook )
  and keyword=abc
  and not keyword={x y z}
}
```

100

This filter will match all entries whose entry type is either <code>@book</code> or <code>@inbook</code> and whose <code>keywords</code> field includes the keyword 'abc' but not 'x y z'. As seen in the above example, all elements are separated by whitespace (spaces, tabs, or line endings). There is no spacing around the equal sign. The logical operators are evaluated with the <code>\ifboolexpr</code> command from the <code>etoolbox</code> package. See the <code>etoolbox</code> manual for details about the syntax. The syntax of the <code>\ifthenelse</code> command from the <code>ifthenelse</code> command from the <code>ifthenelse</code> command in older versions of Biblatex, is still supported. This is the same test using <code>ifthen-like</code> syntax:

```
\defbibfilter{example}{%
  \( \type{book} \or \type{inbook} \)
  \and \keyword{abc}
  \and \not \keyword{x y z}
}
```

Note that custom filters are local to the reference section in which they are used. Use the section filter of \printbibliography to select a different section. This is not possible from within a custom filter.

```
\defbibcheck{\langle name \rangle} {\langle code \rangle}
```

Defines the custom bibliography filter  $\langle name \rangle$ , to be used via the check option of \printbibliography. \defbibcheck is similar in concept to \defbibfilter but much more low-level. Rather than a high-level expression, the  $\langle code \rangle$  is LaTeX code, much like the code used in driver definitions, which may perform arbitrary tests to decide whether or not a given entry is to be printed. The bibliographic data of the respective entry is available when the  $\langle code \rangle$  is executed. Issuing the command \skipentry in the  $\langle code \rangle$  will cause the current entry to be skipped. For example, the following filter will only output entries with an abstract field:

```
\defbibcheck{abstract}{%
  \iffieldundef{abstract}{\skipentry}{}}
...
\printbibliography[check=abstract]
```

The following check will exclude all entries published before the year 2000:

```
\defbibcheck{recent}{%
  \iffieldint{year}
  {\ifnumless{\thefield{year}}{2000}
     {\skipentry}
     {}}
  {\skipentry}}
```

See the author guide, in particular §§ 4.6.2 and 4.6.3, for further details.

101

## 3.6.11 参考文献表内容 Bibliography Contexts

References in a bibliography are cited and printed in a 'context'. The context determines the data which is actually used for an entry. A context consists currently of the following information (the 'context' concept is designed for future extensibility):

### • A specific sorting scheme

The data for an entry can vary depending on the context. This is most obvious in the case of the <code>extra\*</code> fields like <code>extrayear</code> which are generated by the backend according to the order of entries after sorting so that they come out in the expected 'a, b, c' order. This clearly shows that the data in an entry can be different between sorting schemes. If a document contains more than one bibliography list with different sorting schemes, it can happen then that the <code>.bbl</code> contains sorting lists with the same entry but containing different data (a different value for <code>extrayear</code>, for example). The purpose of bibliography contexts is to encapsulate things inside a context so that Biblatex can use the correct entry data. An example is printing a bibliography list with a different sorting order to the global sorting order:

```
\usepackage[sorting=nyt] {biblatex}
\cite{one}
\cite{two}
\printbibliography
\newrefcontext[sorting=yndt]
\cite{one}
\cite{two}
\printbibliography
```

Here, the second use of the citations, along with the \printbibliography command will use data from the context of the 'yndt' sorting scheme which may well be different from the data associated with the default 'nyt' scheme.

```
\begin{refcontext} [\langle key=value, ... \rangle] \end{refcontext}
```

Wraps a bibliography context environment. The options define the context attributes. All context attributes are optional and default to the global settings if absent. The current options are:

```
sorting=⟨name⟩
```

Specify a sorting scheme defined previously with \DeclareSortingScheme. This scheme is used to determine which data to retrieve and/or print for an entry in the commands inside the context.

The refcontext environment cannot be nested and Biblatex will generate an error if you try to do so.

```
\newrefcontext[\langle key=value, ... \rangle]
```

This command is similar to the refcontext environment except that it is a standalone command rather than an environment. It automatically ends the previous context section (if any) and immediately starts a new one. Note that the context section started by the last \newrefcontext command in the document will extend to the very end of the document. Use \endrefcontext if you want to terminate it earlier.

At the beginning of the document, there is always a global context containing global settings for each of the context attributes.

### 3.6.12 动态条目集 Dynamic Entry Sets

In addition to the @set entry type, Biblatex also supports dynamic entry sets defined on a per-document/per-refsection basis. The following command, which may be used in the document preamble or the document body, defines the set  $\langle key \rangle$ :

```
\defbibentryset{\langle key \rangle} {\langle key1, key2, key3, ... \rangle}
```

Biber only

The  $\langle key \rangle$  is the entry key of the set, which is used like any other entry key when referring to the set. The  $\langle key \rangle$  must be unique and it must not conflict with any other entry key. The second argument is a comma-separated list of the entry keys which make up the set. \defbibentryset implies the equivalent of a \nocite command, i.e., all sets which are declared are also added to the bibliography. When declaring the same set more than once, only the first invocation of \defbibentryset will define the set. Subsequent definitions of the same  $\langle key \rangle$  are ignored and work like \nocite $\langle key \rangle$ . Dynamic entry sets defined in the document body are local to the enclosing refsection environment, if any. Otherwise, they are assigned to reference section 0. Those defined in the preamble are assigned to reference section 0. Note that dynamic entry sets require Biber. They will not work with any other backend. See § 3.11.5 for further details.

# 3.7 引用命令 Citation Commands

All citation commands generally take one mandatory and two optional arguments. The  $\langle prenote \rangle$  is text to be printed at the beginning of the citation. This is usually a notice such as 'see' or 'compare'. The  $\langle postnote \rangle$  is text to be printed at the very end of the citation. This is usually a page number. If only one of these arguments is given, it is taken as a postnote. If you want to specify a prenote but no postnote, you need to leave the second optional argument empty, as in \cite[see][]{key}. The  $\langle key \rangle$  argument to all citation commands is mandatory. This is the entry key or a commaseparated list of keys corresponding to the entry keys in the bib file. In sum, all basic citations commands listed further down have the following syntax:

```
\command[\langle prenote \rangle][\langle postnote \rangle] \{\langle keys \rangle\} \langle punctuation \rangle
```

If the autopunct package option from § 3.1.2.1 is enabled, they will scan ahead for any  $\langle punctuation \rangle$  immediately following their last argument. This is useful to avoid spurious punctuation marks after citations. This feature is configured with \DeclareAutoPunctuation, see § 4.7.5 for details.

### 3.7.1 标准命令 Standard Commands

The following commands are defined by the citation style. Citation styles may provide any arbitrary number of specialized commands, but these are the standard commands typically provided by general-purpose styles.

```
\cite[\langle prenote \rangle] [\langle postnote \rangle] {\langle key \rangle} \Cite[\langle prenote \rangle] [\langle postnote \rangle] {\langle key \rangle}
```

These are the bare citation commands. They print the citation without any additions such as parentheses. The numeric and alphabetic styles still wrap the label in square brackets since the reference may be ambiguous otherwise. \Cite is similar to \cite but capitalizes the name prefix of the first name in the citation if the useprefix option is enabled, provided that there is a name prefix and the citation style prints any name at all.

```
\parencite[\langle prenote \rangle] [\langle postnote \rangle] {\langle key \rangle} \Parencite[\langle prenote \rangle] [\langle postnote \rangle] {\langle key \rangle}
```

These commands use a format similar to \cite but enclose the entire citation in parentheses. The numeric and alphabetic styles use square brackets instead. \Parencite is similar to \parencite but capitalizes the name prefix of the first name in the citation if the useprefix option is enabled, provided that there is a name prefix and the citation style prints any name at all.

```
\label{eq:cotone} $$ \footcite[\langle prenote\rangle] [\langle postnote\rangle] {\langle key\rangle} $$ \footcitetext[\langle prenote\rangle] [\langle postnote\rangle] {\langle key\rangle} $$
```

These command use a format similar to \cite but put the entire citation in a footnote and add a period at the end. In the footnote, they automatically capitalize the name prefix of the first name if the useprefix option is enabled, provided that there is a name prefix and the citation style prints any name at all. \footcitetext differs from \footcite in that it uses \footnotetext instead of \footnote.

### 3.7.2 样式相关命令 Style-specific Commands

The following additional citation commands are only provided by some of the citation styles which ship with this package.

```
\textcite [\langle prenote \rangle] [\langle postnote \rangle] {\langle key \rangle} \Textcite [\langle prenote \rangle] [\langle postnote \rangle] {\langle key \rangle}
```

These citation commands are provided by all styles that ship with this package. They are intended for use in the flow of text, replacing the subject of a sentence. They print the authors or editors followed by a citation label which is enclosed in parentheses. Depending on the citation style, the label may be a number, the year of publication, an abridged version of the title, or something else. The numeric and alphabetic styles use square brackets instead of parentheses. In the verbose styles, the label is provided in a footnote. Trailing punctuation is moved between the author or editor names and the footnote mark. \Textcite is similar to \textcite but capitalizes the name prefix of the first name in the citation if the useprefix option is enabled, provided that there is a name prefix.

```
\label{eq:control_smart} $$\operatorname{cite}[\langle prenote \rangle] [\langle postnote \rangle] {\langle key \rangle} $$ \operatorname{Smartcite}[\langle prenote \rangle] [\langle postnote \rangle] {\langle key \rangle} $$
```

Like \parencite in a footnote and like \footcite in the body.

```
\cite*[\langle prenote \rangle][\langle postnote \rangle] \{\langle key \rangle\}
```

This command is provided by all author-year and author-title styles. It is similar to the regular \cite command but merely prints the year or the title, respectively.

```
\protective * [\langle prenote \rangle] [\langle postnote \rangle] {\langle key \rangle}
```

This command is provided by all author-year and author-title styles. It is similar to the regular \parencite command but merely prints the year or the title, respectively.

```
\supercite{\langle key \rangle}
```

This command, which is only provided by the numeric styles, prints numeric citations as superscripts without brackets. It uses \supercitedelim instead of \multicitedelim as citation delimiter. Note that any \langle prenote \rangle and \langle postnote \rangle arguments are ignored. If they are given, \supercite will discard them and issue a warning message.

### 3.7.3 有限标注表 Qualified Citation Lists

This package supports a class of special citation commands called 'multicite' commands. The point of these commands is that their argument is a list of citations where each item forms a fully qualified citation with a pre- and/or postnote. This is particularly useful with parenthetical citations and citations given in footnotes. It is also possible to assign a pre- and/or postnote to the entire list. The multicite commands are built on top of backend commands like \parencite and \footcite. The citation style provides a multicite definition with \DeclareMultiCiteCommand (see § 4.3.1). The following example illustrates the syntax of multicite commands:

```
\parencites[35]{key1}[88--120]{key2}[23]{key3}
```

The format of the arguments is similar to that of the regular citation commands, except that only one citation command is given. If only one optional argument is given for an item in the list, it is taken as a postnote. If you want to specify a prenote but no postnote, you need to leave the second optional argument of the respective item empty:

```
\parencites[35]{key1}[chapter 2 in][]{key2}[23]{key3}
```

In addition to that, the entire citation list may also have a pre- and/or postnote. The syntax of these global notes differs from other optional arguments in that they are given in parentheses rather than the usual brackets:

```
\parencites(and chapter 3)[35]{key1}[78]{key2}[23]{key3}
\parencites(Compare)()[35]{key1}[78]{key2}[23]{key3}
\parencites(See)(and the introduction)[35]{key1}[78]{key2}[23]{key3}
```

Note that the multicite commands keep on scanning for arguments until they encounter a token that is not the start of an optional or mandatory argument. If a left brace or bracket follows a multicite command, you need to mask it by adding \relax or a control space (a backslash followed by a space) after the last valid argument. This will cause the scanner to stop.

```
\parencites[35]{key1}[78]{key2}\relax[...]
\parencites[35]{key1}[78]{key2}\u{...}
```

By default, this package provides the following multicite commands which correspond to regular commands from §§ 3.7.1 and 3.7.2:

```
\cites(\langle multiprenote \rangle) (\langle multipostnote \rangle) [\langle prenote \rangle] [\langle postnote \rangle] {\langle key \rangle} \dots [\langle prenote \rangle] [\langle postnote \rangle] {\langle key \rangle} \\ \cites(\langle multiprenote \rangle) (\langle multipostnote \rangle) [\langle prenote \rangle] [\langle postnote \rangle] {\langle key \rangle} \dots [\langle prenote \rangle] [\langle postnote \rangle] {\langle key \rangle} \\
```

The multicite version of \cite and \Cite, respectively.

```
\label{eq:locality} $$ \operatorname{(\multipostnote)} (\multipostnote) (\multipostnote) [\prenote] [\prenote
```

The multicite version of \parencite and \Parencite, respectively.

```
\label{eq:coto} $$ \cotoites (\langle multiprenote \rangle) (\langle multipostnote \rangle) [\langle prenote \rangle] [\langle postnote \rangle] [\langle key \rangle] ... [\langle prenote \rangle] [\langle postnote \rangle] [\langle key \rangle] $$ \cotoitetexts (\langle multiprenote \rangle) (\langle multipostnote \rangle) [\langle prenote \rangle] [\langle postnote \rangle] $$ \cotoitetexts (\langle multiprenote \rangle) (\langle multipostnote \rangle) [\langle prenote \rangle] [\langle postnote \rangle] $$ \cotoitetexts (\langle multiprenote \rangle) (\langle multipostnote \rangle) [\langle prenote \rangle] $$ \cotoitetexts (\langle multipostnote \rangle) (\langle multipostnote \rangle) $$ \cotoitetexts (\langle multipostnote \rangle) (\langle multipostnote \rangle) $$ \cotoitetexts (\langle multipostnote \rangle) (\langle multipostnote \rangle) $$ \cotoitetexts (\langle multipostnote \rangle) $$ \cotoitetexts
```

The multicite version of  $\footcite$  and  $\footcitetext$ , respectively.

The multicite version of \smartcite and \Smartcite, respectively.

```
\label{eq:locality} $$ \extcites (\langle multiprenote \rangle) (\langle multipostnote \rangle) [\langle prenote \rangle] [\langle postnote \rangle] {\langle key \rangle} ... [\langle prenote \rangle] [\langle postnote \rangle] {\langle key \rangle} ... [\langle prenote \rangle] [\langle postnote \rangle] {\langle key \rangle} ... [\langle prenote \rangle] [\langle postnote \rangle] {\langle key \rangle} ... [\langle prenote \rangle] [\langle postnote \rangle] {\langle key \rangle} ... [\langle prenote \rangle] [\langle postnote \rangle] {\langle key \rangle} ... [\langle prenote \rangle] [\langle postnote \rangle] {\langle key \rangle} ... [\langle prenote \rangle] [\langle postnote \rangle] {\langle key \rangle} ... [\langle prenote \rangle] [\langle postnote \rangle] {\langle key \rangle} ... [\langle prenote \rangle] [\langle postnote \rangle] {\langle key \rangle} ... [\langle prenote \rangle] [\langle postnote \rangle] {\langle key \rangle} ... [\langle prenote \rangle] [\langle postnote \rangle] {\langle key \rangle} ... [\langle prenote \rangle] [\langle postnote \rangle] {\langle key \rangle} ... [\langle prenote \rangle]
```

The multicite version of \textcite and \Textcite, respectively.

```
\langle (multiprenote) \rangle (\langle multipostnote) \rangle [\langle prenote) \rangle [\langle
```

The multicite version of \supercite. This command is only provided by the numeric styles.

## 3.7.4 与样式无关的命令 Style-independent Commands

Sometimes it is desirable to give the citations in the source file in a format that is not tied to a specific citation style and can be modified globally in the preamble. The format of the citations is easily changed by loading a different citation style. However, when using commands such as \parencite or \footcite, the way the citations are integrated with the text is still effectively hard-coded. The idea behind the \autocite command is to provide higher-level citation markup which makes global switching from inline citations to citations given in footnotes (or as superscripts) possible. The \autocite command is built on top of backend commands like \parencite and \footcite. The citation style provides an \autocite definition with \DeclareAutoCiteCommand (see § 4.3.1). This definition may be activated with the autocite package option from § 3.1.2.1. The citation style will usually initialize this package option to a value which is suitable for the style, see § 3.3.1 for details. Note that there are certain limits to high-level citation markup. For example, inline author-year citation schemes often integrate citations so tightly with the text that it is virtually impossible to automatically convert them to footnotes. The \autocite command is only applicable in cases in which you would normally use \parencite or \footcite (or \supercite, with a numeric style). The citations should be given at the end of a sentence or a partial sentence, immediately preceding the terminal punctuation mark, and they should not be a part of the sentence in a grammatical sense (like \textcite, for example).

```
\autocite [\langle prenote \rangle] [\langle postnote \rangle] {\langle key \rangle} \Autocite [\langle prenote \rangle] [\langle postnote \rangle] {\langle key \rangle}
```

In contrast to other citation commands, the \autocite command does not only scan ahead for punctuation marks following its last argument to avoid double punctuation marks, it actually moves them around if required. For example, with autocite = footnote, a trailing punctuation mark will be moved such that the footnote mark is printed after the punctuation. \Autocite is similar to \autocite but capitalizes the name prefix of the first name in the citation if the useprefix option is enabled, provided that there is a name prefix and the citation style prints any name at all.

```
\autocite* [\langle prenote \rangle] [\langle postnote \rangle] {\langle key \rangle} \Autocite* [\langle prenote \rangle] [\langle postnote \rangle] {\langle key \rangle}
```

The starred variants of \autocite do not behave differently from the regular ones. The asterisk is simply passed on to the backend command. For example, if \autocite is configured to use \parencite, then \autocite\* will execute \parencite\*.

```
\autocites (\langle multiprenote \rangle) (\langle multipostnote \rangle) [\langle prenote \rangle] [\langle postnote \rangle] [
```

This is the multicite version of \autocite. It also detects and moves punctuation if required. Note that there is no starred variant. \Autocites is similar to \autocites but capitalizes the name prefix of the first name in the citation if the useprefix option is enabled, provided that there is a name prefix and the citation style prints any name at all.

### 3.7.5 文本命令 Text Commands

The following commands are provided by the core of Biblatex. They are intended for use in the flow of text. Note that all text commands are excluded from citation tracking.

```
\label{eq:citeauthor} $$ \left( \langle prenote \rangle \right) \left(
```

These commands print the authors. Strictly speaking, it prints the labelname list, which may be the author, the editor, or the translator. \Citeauthor is similar to \citeauthor but capitalizes the name prefix of the first name in the citation if the useprefix option is enabled, provided that there is a name prefix. The starred variants effectively force maxcitenames to 1 for just this command on so only print the first name in the labelname list (potentially followed by the "et al" string if there are more names). This allows more natural textual flow when refering to a paper in the singular when otherwise \citeauthor would generate a (naturally plural) list of names.

```
\label{eq:citetitle} $$ \citetitle [\langle prenote \rangle] [\langle postnote \rangle] {\langle key \rangle} $$ $$ \citetitle * [\langle prenote \rangle] [\langle postnote \rangle] {\langle key \rangle} $$
```

This command prints the title. It will use the abridged title in the shorttitle field, if available. Otherwise it falls back to the full title found in the title field. The starred variant always prints the full title.

```
\citeyear [\langle prenote \rangle] [\langle postnote \rangle] {\langle key \rangle} \citeyear* [\langle prenote \rangle] [\langle postnote \rangle] {\langle key \rangle}
```

This command prints the year (year field or year component of date). The starred variant includes the extrayear information, if any.

```
\citedate[\langle prenote \rangle][\langle postnote \rangle] \{\langle key \rangle\}\ \citedate*[\langle prenote \rangle][\langle postnote \rangle] \{\langle key \rangle\}
```

This command prints the full date (date or year). The starred variant includes the extrayear information, if any.

```
\citeurl[\langle prenote \rangle][\langle postnote \rangle] \{\langle key \rangle\}
```

This command prints the url field.

```
\operatorname{parentext}\{\langle text \rangle\}
```

This command wraps the  $\langle text \rangle$  in context sensitive parentheses.

```
\brackettext{\langle text \rangle}
```

This command wraps the  $\langle \textit{text} \rangle$  in context sensitive brackets.

# 3.7.6 特殊命令 Special Commands

The following special commands are also provided by the core of Biblatex.

```
\nocite\{\langle key \rangle\}
```

This command is similar to the standard LaTeX \nocite command. It adds the  $\langle key \rangle$  to the bibliography without printing a citation. If the  $\langle key \rangle$  is an asterisk, all entries available in the bib file are added to the bibliography. Like all other citation commands, \nocite commands in the document body are local to the enclosing refsection environment, if any. In contrast to standard LaTeX, \nocite may also be used in the document preamble. In this case, the references are assigned to reference section 0.

```
fullcite[\langle prenote \rangle][\langle postnote \rangle]\{\langle key \rangle\}
```

This command uses the bibliography driver for the respective entry type to create a full citation similar to the bibliography entry. It is thus related to the bibliography style rather than the citation style.

```
\footfullcite[\langle prenote \rangle][\langle postnote \rangle] \{\langle key \rangle\}
```

Similar to \fullcite but puts the entire citation in a footnote and adds a period at the end.

```
\label{eq:content} $$\operatorname{volcite}[\langle prenote\rangle] {\langle volume\rangle} [\langle page\rangle] {\langle key\rangle} $$ \\ \operatorname{volcite}[\langle prenote\rangle] {\langle volume\rangle} [\langle page\rangle] {\langle key\rangle} $$ \\
```

These commands are similar to \cite and \Cite but intended for references to multivolume works which are cited by volume and page number. Instead of the \( postnote \), they take a mandatory \( volume \) and an optional \( page \) argument. Since they merely compose the postnote and pass it to the \cite command provided by the citation style as a \( postnote \) argument, these commands are style independent. The format of the volume portion is controlled by the field formatting directive volcitevolume, the format of the page/text portion is controlled by the field formatting directive volcitepages (§ 4.10.4). The delimiter printed between the volume portion and the page/text portion may be modified by redefining the macro \volcitedelim (§ 4.10.1).

```
\forall olcites(\langle multiprenote \rangle) (\langle multipostnote \rangle) [\langle prenote \rangle] {\langle volume \rangle} [\langle page \rangle] {\langle key \rangle}
                                                             \dots [\langle prenote \rangle] \{\langle volume \rangle\} [\langle page \rangle] \{\langle key \rangle\}
     \dots [\langle prenote \rangle] \{\langle volume \rangle\} [\langle page \rangle] \{\langle key \rangle\}
                                                          The multicite version of \volcite and \Volcite, respectively.
     \proleite[\langle prenote \rangle] \{\langle volume \rangle\} [\langle page \rangle] \{\langle key \rangle\}
     \Pvolcite[\langle prenote \rangle] \{\langle volume \rangle\} [\langle page \rangle] \{\langle key \rangle\}
                                                          Similar to \volcite but based on \parencite.
\prolement{volcites}(\langle multiprenote \rangle) (\langle multipostnote \rangle) [\langle prenote \rangle] {\langle volume \rangle} [\langle page \rangle] {\langle key \rangle}
                                                             \dots [\langle prenote \rangle] \{\langle volume \rangle\} [\langle page \rangle] \{\langle key \rangle\}
\Pvolcites(\langle multiprenote \rangle) (\langle multipostnote \rangle) [\langle prenote \rangle] {\langle volume \rangle} [\langle page \rangle] {\langle key \rangle}
                                                            \dots [\langle prenote \rangle] \{\langle volume \rangle\} [\langle page \rangle] \{\langle key \rangle\}
                                                          The multicite version of \pvolcite and \Pvolcite, respectively.
     \five [\langle prenote \rangle] \{\langle volume \rangle\} [\langle page \rangle] \{\langle key \rangle\}
\five [\langle prenote \rangle] \{\langle volume \rangle\} [\langle page \rangle] \{\langle key \rangle\}
                                                          Similar to \volcite but based on \footcite and \footcitetext, respectively.
\five 1 = 1  \fvolcites (\langle multiprenote \rangle) (\langle multipostnote \rangle) [\langle prenote \rangle] \{\langle volume \rangle} \] [\langle page \rangle] \{\langle key \rangle}
                                                             ... [\langle prenote \rangle] {\langle volume \rangle} [\langle page \rangle] {\langle key \rangle}
\footnotes (\( \lambda multiprenote \rangle \) (\( \lambda multipostnote \rangle \) [\( \lambda penote \rangle \] [\( \lambda penote \rangle \) [\( \lamb
                                                           ... [\langle prenote \rangle] {\langle volume \rangle} [\langle page \rangle] {\langle key \rangle}
                                                          The multicite version of \fvolcite and \Fvolcite, respectively.
     \scalebox{ } \sc
      \Svolcite[\langle prenote \rangle] \{\langle volume \rangle\} [\langle page \rangle] \{\langle key \rangle\}
                                                          Similar to \volcite but based on \smartcite.
```

```
\langle volcites(\langle multiprenote \rangle) (\langle multipostnote \rangle) [\langle prenote \rangle] {\langle volume \rangle} [\langle page \rangle] {\langle key \rangle}
                         ... [\langle prenote \rangle] {\langle volume \rangle} [\langle page \rangle] {\langle key \rangle}
\langle volcites(\langle multiprenote \rangle) (\langle multipostnote \rangle) [\langle prenote \rangle] {\langle volume \rangle} [\langle page \rangle] {\langle key \rangle}
                         \dots [\langle prenote \rangle] \{\langle volume \rangle\} [\langle page \rangle] \{\langle key \rangle\}
                        The multicite version of \svolcite and \Svolcite, respectively.
  \time [\langle prenote \rangle] \{\langle volume \rangle\} [\langle page \rangle] \{\langle key \rangle\}
  \Tvolcite[\langle prenote \rangle] \{\langle volume \rangle\} [\langle page \rangle] \{\langle key \rangle\}
                        Similar to \volcite but based on \textcite.
\forall volcites (\langle multiprenote \rangle) (\langle multipostnote \rangle) [\langle prenote \rangle] {\langle volume \rangle} [\langle page \rangle] {\langle key \rangle}
                         \dots [\langle prenote \rangle] \{\langle volume \rangle\} [\langle page \rangle] \{\langle key \rangle\}
\Tvolcites(\langle multiprenote \rangle) (\langle multipostnote \rangle) [\langle prenote \rangle] {\langle volume \rangle} [\langle page \rangle] {\langle key \rangle}
                         ... [\langle prenote \rangle] {\langle volume \rangle} [\langle page \rangle] {\langle key \rangle}
                         The multicite version of \tvolcite and \Tvolcite, respectively.
  \langle avolcite[\langle prenote\rangle] \{\langle volume\rangle\} [\langle page\rangle] \{\langle key\rangle\}
  \Lambda \text{volcite}[\langle prenote \rangle] \{\langle volume \rangle\} [\langle page \rangle] \{\langle key \rangle\}
                         Similar to \volcite but based on \autocite.
\langle avolcites(\langle multiprenote \rangle) (\langle multipostnote \rangle) [\langle prenote \rangle] {\langle volume \rangle} [\langle page \rangle] {\langle key \rangle}
                         ... [\langle prenote \rangle] {\langle volume \rangle} [\langle page \rangle] {\langle key \rangle}
\forall \exists v \in (\langle multiprenote \rangle) (\langle multipostnote \rangle) [\langle prenote \rangle] {\langle volume \rangle} [\langle page \rangle] {\langle key \rangle}
                         \dots [\langle prenote \rangle] \{\langle volume \rangle\} [\langle page \rangle] \{\langle key \rangle\}
                        The multicite version of \avolcite and \Avolcite, respectively.
  \notecite[\langle prenote \rangle][\langle postnote \rangle] \{\langle key \rangle\}
```

These commands print the  $\langle prenote \rangle$  and  $\langle postnote \rangle$  arguments but no citation. Instead, a \nocite command is issued for every  $\langle key \rangle$ . This may be useful for authors who incorporate implicit citations in their writing, only giving information not mentioned before in the running text, but who still want to take advantage of the automatic  $\langle postnote \rangle$  formatting and the implicit \nocite function. This is a generic, style-independent citation command. Special citation styles may provide smarter facilities for the same purpose. The capitalized version forces capitalization (note that this is only applicable if the note starts with a command which is sensitive to Biblatex's punctuation tracker).

```
\label{eq:protecond} $$ \protectie[\langle prenote\rangle] [\langle postnote\rangle] {\langle key\rangle} $$ \\ \protectie[\langle prenote\rangle] [\langle postnote\rangle] {\langle key\rangle} $$ $$
```

Similar to \notecite but the notes are printed in parentheses.

```
\fnotecite [\langle prenote \rangle] [\langle postnote \rangle] {\langle key \rangle}
```

Similar to \notecite but the notes are printed in a footnote.

### 3.7.7 底层命令 Low-level Commands

The following commands are also provided by the core of Biblatex. They grant access to all lists and fields at a lower level.

```
\citename[\langle prenote \rangle][\langle postnote \rangle]\{\langle key \rangle\}[\langle format \rangle]\{\langle name\ list \rangle\}
```

The  $\langle format \rangle$  is a formatting directive defined with \DeclareNameFormat. Formatting directives are discussed in § 4.4.2. If this optional argument is omitted, this command falls back to the format citename. The last argument is the name of a  $\langle name \ list \rangle$ , in the sense explained in § 2.2.

```
\citelist[\langle prenote \rangle] [\langle postnote \rangle] {\langle key \rangle} [\langle format \rangle] {\langle literal \ list \rangle}
```

The  $\langle format \rangle$  is a formatting directive defined with \DeclareListFormat. Formatting directives are discussed in § 4.4.2. If this optional argument is omitted, this command falls back to the format citelist. The last argument is the name of a  $\langle literal \ list \rangle$ , in the sense explained in § 2.2.

```
\citefield[\langle prenote \rangle][\langle postnote \rangle]\{\langle key \rangle\}[\langle format \rangle]\{\langle field \rangle\}
```

The  $\langle format \rangle$  is a formatting directive defined with \DeclareFieldFormat. Formatting directives are discussed in § 4.4.2. If this optional argument is omitted, this command falls back to the format citefield. The last argument is the name of a  $\langle field \rangle$ , in the sense explained in § 2.2.

### 3.7.8 其它命令 Miscellaneous Commands

The commands in this section are little helpers related to citations.

This command resets the citation style. This may be useful if the style replaces repeated citations with abbreviations like *ibidem*, *idem*, *op. cit.*, etc. and you want to force a full citation at the beginning of a new chapter, section, or some other location. The command executes a style specific initialization hook defined with the \InitializeCitationStyle command from § 4.3.1. It also resets the internal citation trackers of this package. The reset will affect the \ifciteseen, \ifciteibid, and \ifciteidem tests discussed in § 4.6.2. When used inside a refsection environment, the reset of the citation tracker is local to the current refsection environment. Also see the citereset package option in § 3.1.2.1.

\citereset\* Similar to \citereset but only executes the style's initialization hook, without resetting the internal citation trackers.

- Vise this command to mark manually inserted citations if you mix automatically generated and manual citations. This is particularly useful if the citation style replaces repeated citations by an abbreviation like *ibidem* which may get ambiguous or misleading otherwise. Always use \mancite in the same context as the manual citation, e.g., if the citation is given in a footnote, include \mancite in the footnote. The \mancite command executes a style specific reset hook defined with the \OnManualCitation command from § 4.3.1. It also resets the internal 'ibidem' and 'idem' trackers of this package. The reset will affect the \ifciteibid and \ifciteidem tests discussed in § 4.6.2.
  - \pno This command forces a single page prefix in the \( \postnote \) argument to a citation command. See \( \ \ \ 3.12.3 \) for further details and usage instructions. Note that this command is only available locally in citations and the bibliography.
  - \ppno Similar to \pno but forces a range prefix. See § 3.12.3 for further details and usage instructions. Note that this command is only available locally in citations and the bibliography.
  - \nopp Similar to \pno but suppresses all prefixes. See § 3.12.3 for further details and usage instructions. Note that this command is only available locally in citations and the bibliography.
  - \psq In the \(\phi\)psq argument to a citation command, this command indicates a range of two pages where only the starting page is given. See § 3.12.3 for further details and usage instructions. The suffix printed is the localization string sequens, see § 4.9.2. The spacing inserted between the suffix and the page number may be modified by redefining the macro \sqspace. The default is an unbreakable interword space. Note that this command is only available locally in citations and the bibliography.
  - \psq Similar to \psq but indicates an open-ended page range. See § 3.12.3 for further details and usage instructions. The suffix printed is the localization string sequentes, see § 4.9.2. This command is only available locally in citations and the bibliography.

```
\RN \{ \langle integer \rangle \}
```

This command prints an integer as an uppercase Roman numeral. The formatting applied to the numeral may be modified by redefining the macro \RNfont.

```
\Rn \{ \langle integer \rangle \}
```

Similar to \RN but prints a lowercase Roman numeral. The formatting applied to the numeral may be modified by redefining the macro \Rnfont.

# 3.7.9 与natbib兼容的命令 natbib Compatibility Commands

The natbib package option loads a natbib compatibility module. The module defines aliases for the citation commands provided by the natbib package. This includes aliases for the core citation commands \citet and \citep as well as the

variants \citealt and \citealp. The starred variants of these commands, which print the full author list, are also supported. The \cite command, which is handled in a particular way by natbib, is not treated in a special way. The text commands (\citeauthor, \citeyear, etc.) are also supported, as are all commands which capitalize the name prefix (\Citet, \Citep, \Citeauthor, etc.). Aliasing with \defcitealias, \citetalias, and \citepalias is possible as well. Note that the compatibility commands will not emulate the citation format of the natbib package. They merely alias natbib's commands to functionally equivalent facilities of the Biblatex package. The citation format depends on the main citation style. However, the compatibility style will adapt \nameyeardelim to match the default style of the natbib package.

### 3.7.10 类似mcite给的标注命令

Biber only

The mcite package option loads a special citation module which provides mcite/mciteplus-like citation commands. Strictly speaking, what the module provides are wrappers for the commands of the main citation style. For example, the following command:

```
\mcite{key1, setA, *keyA1, *keyA2, *keyA3, key2, setB, *keyB1, *keyB2, *keyB3}
```

is essentially equivalent to this:

```
\defbibentryset{setA}{keyA1, keyA2, keyA3}%
\defbibentryset{setB}{keyB1, keyB2, keyB3}%
\cite{key1, setA, key2, setB}
```

The \mcite command will work with any style since the \cite backend command is controlled by the main citation style as usual. The mcite module provides wrappers for the standard commands in §§ 3.7.1 and 3.7.2. See table 7 for an overview. Pre and postnotes as well as starred variants of all commands are also supported. The parameters will be passed to the backend command. For example:

```
\mcite*[pre][post]{setA, *keyA1, *keyA2, *keyA3}
```

will execute:

```
\defbibentryset{setA}{keyA1, keyA2, keyA3}%
\cite*[pre][post]{setA}
```

Note that the mcite module is not a compatibility module. It provides commands which are very similar but not identical in syntax and function to mcite's commands. When migrating from mcite/mciteplus to Biblatex, legacy files must be updated. With mcite, the first member of the citation group is also the identifier of the group as a whole. Borrowing an example from the mcite manual, this group:

```
\cite{glashow, *salam, *weinberg}
```

Standard Command	mcite-like Command \mcite	
\cite		
\Cite	\Mcite	
\parencite	\mparencite	
\Parencite	\Mparencite	
\footcite	\mfootcite	
\footcitetext	\mfootcitetext	
\textcite	\mtextcite	
\Textcite	\Mtextcite	
\supercite	\msupercite	

Table 6: mcite-like commands

consists of three entries and the entry key of the first one also serves as identifier of the entire group. In contrast to that, a Biblatex entry set is an entity in its own right. Therefore, it requires a unique entry key which is assigned to the set as it is defined:

```
\mcite{set1, *glashow, *salam, *weinberg}
```

Once defined, an entry set is handled like any regular entry in a bib file. When using one of the numeric styles which ship with biblatex and activating its subentry option, it is even possible to refer to set members. See table 7 for some examples. Restating the original definition of the set is redundant, but permissible. In contrast to mciteplus, however, restating a part of the original definition is invalid. Use the entry key of the set instead.

# 3.8 本地化命令 Localization Commands

The Biblatex package provides translations for key terms such as 'edition' or 'volume' as well as definitions for language specific features such as the date format and ordinals. These definitions, which are loaded automatically, may be modified or extended in the document preamble or the configuration file with the commands introduced in this section.

```
\DefineBibliographyStrings{\language\} {\language\}} \definitions\}
```

This command is used to define localization strings. The  $\langle language \rangle$  must be a language name known to the babel/polyglossia packages, i. e., one of the identifiers listed in table 2 on page 34. The  $\langle definitions \rangle$  are  $\langle key \rangle = \langle value \rangle$  pairs which assign an expression to an identifier:

```
\DefineBibliographyStrings{american}{%
  bibliography = {Bibliography},
  shorthands = {Abbreviations},
  editor = {editor},
  editors = {editors},
```

Input	Output	Comment
\mcite{set1,*glashow,*salam,*weinberg}	[1]	Defining and citing the set
\mcite{set1}	[1]	Subsequent citation of the set
\cite{set1}	[1]	Regular \cite works as usual
<pre>\mcite{set1,*glashow,*salam,*weinberg}</pre>	[1]	Redundant, but permissible
\mcite{glashow}	[1a]	Citing a set member
\cite{weinberg}	[1c]	Regular \cite works as well

Table 7: mcite-like syntax (sample output with style = numeric and subentry option)

A complete list of all keys supported by default is given is § 4.9.2. Note that all expressions should be capitalized as they usually are when used in the middle of a sentence. The Biblatex package will automatically capitalize the first word when required at the beginning of a sentence. Expressions intended for use in headings should be capitalized in a way that is suitable for titling. In contrast to \DeclareBibliographyStrings, \DefineBibliographyStrings overrides both the full and the abbreviated version of the string. See § 4.9.1 for further details.

```
\DefineBibliographyExtras\{\langle language \rangle\}\{\langle code \rangle\}
```

This command is used to adapt language specific features such as the date format and ordinals. The  $\langle language \rangle$  must be a language name known to the babel/polyglossia packages. The  $\langle code \rangle$ , which may be arbitrary LaTeX code, will usually consist of redefinitions of the formatting commands from § 3.9.2.

```
\UndefineBibliographyExtras\{\langle language \rangle\}\{\langle code \rangle\}
```

This command is used to restore the original definition of any commands modified with \DefineBibliographyExtras. If a redefined command is included in § 3.9.2, there is no need to restore its previous definition since these commands are adapted by all language modules anyway.

```
\DefineHyphenationExceptions { \language \rangle } \ \language \rangle \}
```

This is a LaTeX frontend to TeX's \hyphenation command which defines hyphenation exceptions. The  $\langle language \rangle$  must be a language name known to the babel/polyglossia packages. The  $\langle text \rangle$  is a whitespace-separated list of words. Hyphenation points are marked with a dash:

```
\DefineHyphenationExceptions{american}{%
  hy-phen-ation ex-cep-tion
}
```

### $\NewBibliographyString{\langle key \rangle}$

This command declares new localization strings, i. e., it initializes a new  $\langle key \rangle$  to be used in the  $\langle definitions \rangle$  of \DefineBibliographyStrings. The  $\langle key \rangle$  argument may also be a comma-separated list of key names. The keys listed in § 4.9.2 are defined by default.

# 3.9 格式命令 Formatting Commands

The commands and facilities presented in this section may be used to adapt the format of citations and the bibliography.

### 3.9.1 一般命令和钩子 Generic Commands and Hooks

The commands in this section may be redefined with \renewcommand in the document preamble. Note that all commands starting with \mk... take one argument. All of these commands are defined in biblatex.def.

\bibsetup Arbitrary code to be executed at the beginning of the bibliography, intended for commands which affect the layout of the bibliography.

\bibfont Arbitrary code setting the font used in the bibliography. This is very similar to \bibsetup but intended for switching fonts.

\citesetup Arbitrary code to be executed at the beginning of each citation command.

\newblockpunct The separator inserted between 'blocks' in the sense explained in § 4.7.1. The default definition is controlled by the package option block (see § 3.1.2.1).

\newunitpunct The separator inserted between 'units' in the sense explained in § 4.7.1. This will usually be a period or a comma plus an interword space. The default definition is a period and a space.

\finentrypunct The punctuation printed at the very end of every bibliography entry, usually a period.

The default definition is a period.

\entrysetpunct The punctuation printed between bibliography subentries of an entry set. The default Biber only definition is a semicolon and a space.

This delimiter controls the spacing between the elements which make up a name part.

It is inserted automatically after the first name element if the element is less than three characters long and before the last element. The default definition is an interword space penalized by the value of the highnamepenalty counter (§ 3.9.3). Please refer to § 3.12.4 for further details.

\bibnamedelimb This delimiter is inserted between the elements which make up a name part where bibnamedelima does not apply. The default definition is an interword space penalized by the value of the lownamepenalty counter (§ 3.9.3). Please refer to § 3.12.4 for further details.

\bibnamedelimc This delimiter controls the spacing between name parts. It is inserted between the name prefix and the last name if useprefix=true. The default definition is an interword space penalized by the value of the highnamepenalty counter (§ 3.9.3). Please refer to § 3.12.4 for further details.

\bibnamedelimd This delimiter is inserted between all name parts where \bibnamedelimc does not apply. The default definition is an interword space penalized by the value of the lownamepenalty counter (§ 3.9.3). Please refer to § 3.12.4 for further details.

\bibnamedelimi This delimiter replaces \bibnamedelima/b after initials. Note that this only applies Biber only to initials given as such in the bib file, not to the initials automatically generated by Biblatex which use their own set of delimiters.

\bibinitperiod The punctuation inserted after initials unless \bibinithyphendelim applies. The Biber only default definition is a period (\addot). Please refer to § 3.12.4 for further details.

\bibinitdelim The spacing inserted between multiple initials unless \bibinithyphendelim applies. The default definition is an unbreakable interword space. Please refer to § 3.12.4 for further details.

\bibinithyphendelim The punctuation inserted between the initials of hyphenated name parts, replacing \bibinitperiod and \bibinitdelim. The default definition is a period followed by an unbreakable hyphen. Please refer to § 3.12.4 for further details.

\bibindexnamedelima Replaces \bibnamedelima in the index.

\bibindexnamedelimb Replaces \bibnamedelimb in the index.

\bibindexnamedelimc Replaces \bibnamedelimc in the index.

\bibindexnamedelimd Replaces \bibnamedelimd in the index.

\bibindexnamedelimi Replaces \bibnamedelimi in the index.

\bibindexinitperiod Replaces \bibinitperiod in the index.

\bibindexinitdelim Replaces \bibinitdelim in the index.

\bibindexinithyphendelim Replaces \bibinithyphendelim in the index.

\revsdnamepunct The punctuation to be printed between the first and last name parts when a name is reversed. Here is an example showing a name with the default comma as \revsdnamedelim:

Jones, Edward

This command should be used with \bibnamedelimd as a reversed-name separator in formatting directives for name lists. Please refer to § 3.12.4 for further details.

\bibnamedash The dash to be used as a replacement for recurrent authors or editors in the bibliography. The default is an 'em' or an 'en' dash, depending on the indentation of the list of references.

\labelnamepunct The separator printed after the name used for alphabetizing in the bibliography
(author or editor, if the author field is undefined). With the default styles,
this separator replaces \newunitpunct at this location. The default definition is
\newunitpunct, i. e., it is not handled differently from regular unit punctuation.

\subtitlepunct The separator printed between the fields title and subtitle, booktitle and booksubtitle, as well as maintitle and mainsubtitle. With the default styles, this separator replaces \newunitpunct at this location. The default definition is \newunitpunct, i. e., it is not handled differently from regular unit punctuation.

The separator between the word "in" and the following title in entry types such as @article, @inbook, @incollection, etc. The default definition is a colon plus an interword space (e.g., "Article, in: Journal" or "Title, in: Book"). Note that this is the separator string, not only the punctuation mark. If you don't want a colon after "in", \intitlepunct should still insert a space.

\bibpagespunct The separator printed before the pages field. The default is a comma plus an interword space.

\bibpagerefpunct The separator printed before the pageref field. The default is an interword space.

\multinamedelim The delimiter printed between multiple items in a name list like author or editor if there are more than two names in the list. The default is a comma plus an interword space. See \finalnamedelim for an example.<sup>20</sup>

\finalnamedelim The delimiter printed instead of \multinamedelim before the final name in a name list. The default is the localized term 'and', separated by interword spaces. Here is an example:

Michel Goossens, Frank Mittelbach and Alexander Samarin Edward Jones and Joe Williams

The comma in the first example is the \multinamedelim whereas the string 'and' in both examples is the \finalnamedelim. See also \finalandcomma in § 3.9.2.

\revsdnamedelim An extra delimiter printed after the first name in a name list if the first name is reversed. The default is an empty string, i. e., no extra delimiter will be printed. Here is an example showing a name list with a comma as \revsdnamedelim:

Jones, Edward, and Joe Williams

In this example, the comma after 'Edward' is the \revsdnamedelim whereas the string 'and' is the \finalnamedelim, printed in addition to the former.

<sup>&</sup>lt;sup>20</sup>Note that \multinamedelim is not used at all if there are only two names in the list. In this case, the default styles use the \finalnamedelim.

- \andothersdelim The delimiter printed before the localization string 'andothers' if a name list like author or editor is truncated. The default is an interword space.
- \multilistdelim The delimiter printed between multiple items in a literal list like publisher or location if there are more than two items in the list. The default is a comma plus an interword space. See \multinamedelim for further explanation.
- \finallistdelim The delimiter printed instead of \multilistdelim before the final item in a literal list. The default is the localized term 'and', separated by interword spaces. See \finalnamedelim for further explanation.
- \andmoredelim The delimiter printed before the localization string 'andmore' if a literal list like publisher or location is truncated. The default is an interword space.
- \multicitedelim The delimiter printed between citations if multiple entry keys are passed to a single citation command. The default is a semicolon plus an interword space.
- \supercitedelim Similar to \multicitedelim, but used by the \supercite command only. The default is a comma.
- \compcitedelim Similar to \multicitedelim, but used by certain citation styles when 'compressing' multiple citations. The default definition is a comma plus an interword space.
- \textcitedelim Similar to \multicitedelim, but used by \textcite and related commands (§ 3.7.2). The default is a comma plus an interword space. The standard styles modify this provisional definition to ensure that the delimiter before the final citation is the localized term 'and', separated by interword spaces. See also \finalandcomma and \finalandsemicolon in § 3.9.2.
- \nametitledelim The delimiter printed between the author/editor and the title by author-title and some verbose citation styles. The default definition is a comma plus an interword space.
- \nameyeardelim The delimiter printed between the author/editor and the year by author-year citation styles. The default definition is an interword space.
- \labelalphaothers A string to be appended to the non-numeric portion of the labelalpha field (i.e., the field holding the citation label used by alphabetic citation styles) if the number of authors/editors exceeds the maxalphanames threshold or the author/editor list was truncated in the bib file with the keyword 'and others'. This will typically be a single character such as a plus sign or an asterisk. The default is a plus sign. This command may also be redefined to an empty string to disable this feature. In any case, it must be redefined in the preamble.
- \sortalphaothers Similar to \labelalphaothers but used in the sorting process. Setting it to a Biber only different value is advisable if the latter contains formatting commands, for example:

```
\renewcommand*{\labelalphaothers}{\textbf{+}}
\renewcommand*{\sortalphaothers}{+}
```

If \sortalphaothers is not redefined, it defaults to \labelalphaothers.

\prenotedelim The delimiter printed after the \(\langle prenote\rangle\) argument of a citation command. See \(\xi\) 3.7 for details. The default is an interword space.

\postnotedelim The delimiter printed before the \(\langle postnote \rangle\) argument of a citation command. See § 3.7 for details. The default is a comma plus an interword space.

\mkbibnamelast {  $\langle text \rangle$  } This command, which takes one argument, is used to format the last name of all authors, editors, translators, etc.

\mkbibnamefirst{\langle text\rangle} Similar to \mkbibnamelast, but intended for the first name.

\mkbibnameprefix  $\{\langle text \rangle\}$  Similar to \mkbibnamelast, but intended for the name prefix.

 $\mbox{\label{limits} Similar to \mbbibnamelast, but intended for the name affix.}$ 

\relatedpunct The separator between the relatedtype bibliography localization string and the data from the first related entry. Here is an example with \relatedpunct set to a dash:

```
A. Smith. Title. 2000, (Orig. pub. as-Origtitle)
```

\relateddelim The separator between the data of multiple related entries. The default definition is an optional dot plus linebreak. Here is an example where volumes A-E are related entries of the 5 volume main work:

```
Donald E. Knuth. Computers & Typesetting. 5 vols. Reading, Mass.: Addison-
Wesley, 1984-1986.
Vol. A: The TEXbook. 1984.
```

Vol. B: TEX: The Program. 1986.

Vol. C: The METAFONTbook. By. 1986.

Vol. D: METAFONT: The Program. 1986.

Vol. E: Computer Modern Typefaces. 1986.

### 3.9.2 语言相关命令 Language-specific Commands

The commands in this section are language specific. When redefining them, you need to wrap the new definition in a \DeclareBibliographyExtras command (in an .lbx file) or a \DefineBibliographyExtras command (user documents), see § 3.8 for details. Note that all commands starting with \mk... take one or more arguments.

\bibrangedash The language specific dash to be used for ranges of numbers.

\bibrangessep Biber only

The language specific separator to be used between multiple ranges.

\bibdatedash The language specific dash to be used for date ranges. \mkbibdatelong Takes the names of three field as arguments which correspond to three date components (in the order year/month/day) and uses their values to print the date in the language specific long date format. \mkbibdateshort Similar to \mkbibdatelong but using the language specific short date format. \finalandcomma Prints the comma to be inserted before the final 'and' in a list, if applicable in the respective language. Here is an example: Michel Goossens, Frank Mittelbach, and Alexander Samarin \finalandcomma is the comma before the word 'and'. also \multinamedelim, \finalnamedelim, \textcitedelim, and \revsdnamedelim in § 3.9.1. \finalandsemicolon Prints the semicolon to be inserted before the final 'and' in a list of lists, if applicable in the respective language. Here is an example: Goossens, Mittelbach, and Samarin; Bertram and Wenworth; and Knuth \finalandsemicolon is the semicolon before the word 'and'. See also \textcitedelim in § 3.9.1.  $\mbox{\mbox{$\mbox{mkbibordinal}}} \langle \mbox{\mbox{$\mbox{$integer$}$}} \rangle$ This command, which takes an integer as its argument, prints an ordinal number.  $\mbox{\mbox{$\mbox{mkbibmascord}$}}\$ Similar to \mkbibordinal, but prints a masculine ordinal, if applicable in the respective language. \mkbibfemord{\langle integer\rangle} Similar to \mkbibordinal, but prints a feminine ordinal, if applicable in the respective language. \mkbibneutord{\langle integer\rangle} Similar to \mkbibordinal, but prints a neuter ordinal, if applicable in the respective

\mkbibordedition{\langle integer \rangle }

language.

Similar to \mkbibordinal, but intended for use with the term 'edition'.

\mkbibordseries{\langle integer\rangle}

Similar to \mkbibordinal, but intended for use with the term 'series'.

### 3.9.3 尺寸和计数器 Lengths and Counters

The length registers and counters in this section may be changed in the document preamble with \setlength and \setcounter, respectively.

\bibhang

The hanging indentation of the bibliography, if applicable. This length is initialized to \parindent at load-time.

\biblabelsep

The horizontal space between entries and their corresponding labels in the bibliography. This only applies to bibliography styles which print labels, such as the numeric and alphabetic styles. This length is initialized to twice the value of \labelsep at load-time.

\bibitemsep

The vertical space between the individual entries in the bibliography. This length is initialized to \itemsep at load-time. Note that \bibitemsep, \bibnamesep, and \bibinitsep obey the rules for \addvspace, that is, when vertical space introduced by any of these commands immediately follows on from space introduced by another of them, the resulting total space is equal to the largest of them.

\bibnamesep

Vertical space to be inserted between two entries in the bibliography whenever an entry starts with a name which is different from the initial name of the previous entry. The default value is zero. Setting this length to a positive value greater than \bibitemsep will group the bibliography by author/editor name. Note that \bibitemsep, \bibnamesep, and \bibinitsep obey the rules for \addvspace, that is, when vertical space introduced by any of these commands immediately follows on from space introduced by another of them, the resulting total space is equal to the largest of them.

\bibinitsep

Vertical space to be inserted between two entries in the bibliography whenever an entry starts with a letter which is different from the initial letter of the previous entry. The default value is zero. Setting this length to a positive value greater than \bibitemsep will group the bibliography alphabetically. Note that \bibitemsep, \bibnamesep, and \bibinitsep obey the rules for \addvspace, that is, when vertical space introduced by any of these commands immediately follows on from space introduced by another of them, the resulting total space is equal to the largest of them.

\bibparsep

The vertical space between paragraphs within an entry in the bibliography. The default value is zero.

abbrypenalty This counter, which is used by the localization modules, holds the penalty used in short or abbreviated localization strings. For example, a linebreak in expressions such as "et al." or "ed. by" is unfortunate, but should still be possible to prevent overfull boxes. This counter is initialized to \hyphenpenalty at load-time. The idea is making TeX treat the whole expression as if it were a single, hyphenatable word as far as line-breaking is concerned. If you dislike such linebreaks, use a higher value. If you do not mind them at all, set this counter to zero. If you want to suppress them unconditionally, set it to 'infinite' (10 000 or higher).<sup>21</sup>

highnamepenalty This counter holds a penalty affecting line-breaking in names. Please refer to §§ 3.12.4 and 3.9.1 for explanation. The counter is initialized to \hyphenpenalty at load-time. Use a higher value if you dislike the respective linebreaks. If you do not mind them at all, set this counter to zero. If you prefer the traditional BibTeX behavior (no linebreaks at highnamepenalty breakpoints), set it to 'infinite' (10 000 or higher).

lownamepenalty Similar to highnamepenalty. Please refer to §§ 3.12.4 and 3.9.1 for explanation. The counter is initialized to half the \hyphenpenalty at load-time. Use a higher value if you dislike the respective linebreaks. If you do not mind them at all, set this counter to zero.

### 3.9.4 多用途命令 All-purpose Commands

The commands in this section are all-purpose text commands which are generally available, not only in citations and the bibliography.

\bibellipsis An ellipsis symbol with brackets: '[...]'.

\noligature Disables ligatures at this position and adds some space. Use this command to break up standard ligatures like 'fi' and 'fl'. It is similar to the " | shorthand provided by some language modules of the babel/polyglossia packages.

\hyphenate A conditional hyphen. In contrast to the standard \- command, this one allows hyphenation in the rest of the word. It is similar to the "- shorthand provided by some language modules of the babel/polyglossia packages.

\hyphen An explicit, breakable hyphen intended for compound words. In contrast to a literal '-', this command allows hyphenation in the rest of the word. It is similar to the "= shorthand provided by some language modules of the babel/polyglossia packages.

\nbhyphen An explicit, non-breakable hyphen intended for compound words. In contrast to a literal '-', this command does not permit line breaks at the hyphen but still allows hyphenation in the rest of the word. It is similar to the "~ shorthand provided by some language modules of the babel/polyglossia packages.

\nohyphenation A generic switch which suppresses hyphenation locally. Its scope should normally be confined to a group.

 $<sup>^{21}</sup>$  The default values assigned to abbrvpenalty, lownamepenalty, and highnamepenalty are deliberately very low to prevent overfull boxes. This implies that you will hardly notice any effect on line-breaking if the text is set justified. If you set these counters to 10 000 to suppress the respective breakpoints, you will notice their effect but you may also be confronted with overfull boxes. Keep in mind that line-breaking in the bibliography is often more difficult than in the body text and that you can not resort to rephrasing a sentence. In some cases it may be preferable to set the entire bibliography \raggedright to prevent suboptimal linebreaks. In this case, even the fairly low default penalties will make a visible difference.

```
\text{text}
```

Similar to \nohyphenation but restricted to the  $\langle text \rangle$  argument.

```
\mathbb{C} \left( integer \right)
```

Takes an integer in the range 1-702 as its argument and converts it to a string as follows: 1=a, ..., 26=z, 27=aa, ..., 702=zz. This is intended for use in formatting directives for the extravear and extraalpha fields.

```
\mkbibacro{\langle text\rangle}
```

Generic command which typesets an acronym using the small caps variant of the current font, if available, and as-is otherwise. The acronym should be given in uppercase letters.

```
\autocap{\langle character\rangle}
```

Automatically converts the  $\langle character \rangle$  to its uppercase form if Biblatex's punctuation tracker would capitalize a localization string at the current location. This command is robust. It is useful for conditional capitalization of certain strings in an entry. Note that the  $\langle character \rangle$  argument is a single character given in lowercase. For example:

```
\autocap{s}pecial issue
```

will yield 'Special issue' or 'special issue', as appropriate. If the string to be capitalized starts with an inflected character given in Ascii notation, include the accent command in the  $\langle character \rangle$  argument as follows:

```
\autocap{\'e}dition sp\'eciale
```

This will yield 'Édition spéciale' or 'édition spéciale'. If the string to be capitalized starts with a command which prints a character, such as ae or e simply put the command in the character argument:

```
\autocap{\oe}uvres
```

This will yield 'Œuvres' or 'œuvres'.

# 3.10 语言相关注意点 Language-specific Notes

The facilities discussed in this section are specific to certain localization modules.

# 3.10.1 美语 American

The American localization module uses \uspunctuation from § 4.7.5 to enable 'American-style' punctuation. If this feature is enabled, all trailing commas and periods after \mkbibquote will be moved inside the quotes. If you want to disable this feature, use \stdpunctuation as follows:

```
\DefineBibliographyExtras{american}{%
  \stdpunctuation
}
```

By default, the 'American punctuation' feature is enabled by the american localization module only. The above code is only required if you want American localization without American punctuation. Since standard punctuation is the package default, it would be redundant with any other language.

It is highly advisable to always specify american, british, australian, etc. rather than english when loading the babel/polyglossia packages to avoid any possible confusion. Older versions of the babel package used to treat english as an alias for british; more recent ones treat it as an alias for american. The biblatex package essentially treats english as an alias for american, except for the above feature which is only enabled if american is requested explicitly.

# 3.10.2 西班牙语 Spanish

Handling the word 'and' is more difficult in Spanish than in the other languages supported by this package because it may be 'y' or 'e', depending on the initial sound of the following word. Therefore, the Spanish localization module does not use the localization string 'and' but a special internal 'smart and' command. The behavior of this command is controlled by the smartand counter.

Smartand This counter controls the behavior of the internal 'smart and' command. When set to 1, it prints 'y' or 'e', depending on the context. When set to 2, it always prints 'y'. When set to 3, it always prints 'e'. When set to 0, the 'smart and' feature is disabled. This counter is initialized to 1 at load-time and may be changed in the preamble. Note that setting this counter to a positive value implies that the Spanish localization module ignores \finalnamedelim and \finallistdelim.

\forceE Use this command in bib files if Biblatex gets the 'and' before a certain name wrong.

As its name suggests, it will enforce 'e'. This command must be used in a special way to prevent confusing BibTeX. Here is an example:

```
author = {Edward Jones and Eoin Maguire},
author = {Edward Jones and {\forceE{E}}oin Maguire},
```

Note that the initial letter of the respective name component is given as an argument to \forceE and that the entire construct is wrapped in an additional pair of curly braces.

\forceY Similar to \forceE but enforces 'y'.

## 3.10.3 希腊语 Greek

The Greek localization module requires UTF-8 support. It will not work with any other encoding. Generally speaking, the Biblatex package is compatible with the inputence

package and with XeLaTeX. The ucs package will not work. Since inputenc's standard utf8 module is missing glyph mappings for Greek, this leaves Greek users with XeLaTeX. Note that you may need to load additional packages which set up Greek fonts. As a rule of thumb, a setup which works for regular Greek documents should also work with Biblatex. However, there is one fundamental limitation. As of this writing, Biblatex has no support for switching scripts. Greek titles in the bibliography should work fine, provided that you use Biber as a backend, but English and other titles in the bibliography may be rendered in Greek letters. If you need multi-script bibliographies, using XeLaTeX is the only sensible choice.

### 3.10.4 **俄语 Russian**

Like the Greek localization module, the Russian module also requires UTF-8 support. It will not work with any other encoding.

# 3.11 用法注意点 Usage Notes

The following sections give a basic overview of the Biblatex package and discuss some typical usage scenarios.

#### 3.11.1 概述 Overview

Using the Biblatex package is slightly different from using traditional BibTeX styles and related packages. Before we get to specific usage scenarios, we will therefore have a look at the structure of a typical document first:

```
\documentclass{...}
\usepackage[...]{biblatex}
\addbibresource{bibfile.bib}
\begin{document}
\cite{...}
...
\printbibliography
\end{document}
```

With traditional BibTeX, the \bibliography command serves two purposes. It marks the location of the bibliography and it also specifies the bib file(s). The file extension is omitted. With Biblatex, resources are specified in the preamble with \addbibresource using the full name with .bib suffix. The bibliography is printed using the \printbibliography command which may be used multiple times (see § 3.6 for details). The document body may contain any number of citation commands (§ 3.7). Processing this example file requires that a certain procedure be followed. Suppose our example file is called example.tex and our bibliographic data is in bibfile.bib. The procedure, then, is as follows:

#### 3.11.1.1 Biber

- 1. Run latex on example.tex. If the file contains any citations, Biblatex will request the respective data from Biber by writing commands to the auxiliary file example.bcf.
- 2. Run biber on example.bcf. Biber will retrieve the data from bibfile. bib and write it to the auxiliary file example.bbl in a format which can be processed by Biblatex.
- 3. Run latex on example.tex. Biblatex will read the data from example. bbl and print all citations as well as the bibliography.

#### 3.11.1.2 BibTeX

- 1. Run latex on example.tex. If the file contains any citations, Biblatex will request the respective data from BibTeX by writing commands to the auxiliary file example.aux.
- 2. Run bibtex on example.aux. BibTeX will retrieve the data from bibfile. bib and write it to the auxiliary file example.bbl in a format which can be processed by Biblatex.
- 3. Run latex on example.tex. Biblatex will read the data from example. bbl and print all citations as well as the bibliography.

Whenever a reference to a work which has not been cited before is added, this procedure must be repeated. This is also the case if the last reference to a work which has been cited before is removed because some citation labels may change in this case. In contrast to traditional BibTeX, there is normally no need to run latex twice after running the backend as far as the handling of bibliographic data is concerned.<sup>22</sup>

Note that when using BibTeX as the backend this only applies to the most basic case. Using the xref field or the entryset field may require an additional LaTeX/BibTeX/LaTeX cycle. Some other facilities provided by Biblatex may also require an additional latex run to get certain references and the page tracking right. In this case, the usual warning messages such as "There were undefined references" and "Label(s) may have changed. Rerun to get cross-references right" will be printed.

### 3.11.2 辅助文件 Auxiliary Files

**3.11.2.1 Biber** The Biblatex package uses one auxiliary bcf file only. Even if there are citation commands in a file included via \include, you only need to run Biber on the main bcf file. All information Biber needs is in the bcf file, including information about all refsections if using multiple refsection environments (see § 3.11.3).

BibTeX only

<sup>&</sup>lt;sup>22</sup>That is, unless the defernumbers package option is enabled. See § 4.1

3.11.2.2 BibTeX By default, the Biblatex package uses the main aux file only. Even if there are citation commands in a file included via \include, which has its own aux file, you only need to run BibTeX on the main aux file. If you are using refsection environments in a document (see § 3.11.3) Biblatex will create one additional aux file for every refsection environment. In this case, you also need to run bibtex on each additional aux file. The name of the additional aux files is the base name of the main input file with the string -blx and a running number appended at the end. The Biblatex package issues a warning listing the files which require an additional BibTeX run. With the basic example presented in § 3.11.1, it would issue the following warning:

```
Package biblatex Warning: Please (re)run BibTeX on the file(s):
(biblatex) example.aux
(biblatex) and rerun LaTeX afterwards.
```

If the input file contained three refsection environments, the warning would read as follows:

```
Package biblatex Warning: Please (re)run BibTeX on the file(s):
(biblatex) example1-blx.aux
(biblatex) example2-blx.aux
(biblatex) example3-blx.aux
(biblatex) and rerun LaTeX afterwards.
```

Apart from these aux files, Biblatex uses an additional bib file with the same suffix to pass certain control parameters to BibTeX. In the example above, this file would be named example-blx.bib. In the event of a file name conflict, you can change the suffix by redefining the macro \blxauxsuffix in the document preamble. When using Biber, Biblatex writes a control file named example.bcf and ignores \blxauxsuffix. There is also no auxiliary bib file in this case.

Note that Biblatex will not overwrite any files it did not create. All auxiliary files created automatically by this package start with a special signature line. Before overwriting a file (excluding the main <code>aux</code> file, which is managed by LaTeX), Biblatex inspects the first line of the file to make sure that there is no file name conflict. If the file in question is missing the signature line, Biblatex will immediately issue an error message and abort before opening the output stream. In this case you should delete any spurious files accidentally left in the working directory. If the error persists, there may be a file name conflict with a file found in one of the TeX installation trees. Since the installation trees usually do not contain any <code>aux</code> files and the string <code>-blx</code> is fairly exotic in the name of a <code>blb</code> file, this is rather unlikely but theoretically possible. If you find out that this is indeed the case, you should redefine <code>\blxauxsuffix</code> permanently in the Biblatex configuration file, <code>blblatex.cfg</code>.

# 3.11.3 多个参考文献表 Multiple Bibliographies

In a collection of articles by different authors, such as a conference proceedings volume for example, it is very common to have one bibliography for each article rather than a global one for the entire book. In the example below, each article would be presented as a separate \chapter with its own bibliography.

Note that with the BibTeX backend, Biblatex creates one additional aux file for BibTeX only every refsection environment. These files have to be processed by BibTeX as well, see § 3.11.2 for details.

```
\documentclass{...}
\usepackage{biblatex}
\addbibresource{...}
\begin{document}
\chapter{...}
\begin{refsection}
...
\printbibliography[heading=subbibliography]
\end{refsection}
\chapter{...}
\begin{refsection}
...
\printbibliography[heading=subbibliography]
\end{refsection}
...
\printbibliography[heading=subbibliography]
\end{refsection}
\end{document}
```

If \printbibliography is used inside a refsection environment, it automatically restricts the scope of the list of references to the enclosing refsection environment. For a cumulative bibliography which is subdivided by chapter but printed at the end of the book, use the section option of \printbibliography to select a reference section, as shown in the next example.

```
\documentclass{...}
\usepackage{biblatex}
\defbibheading{subbibliography}{%
  \section*{References for Chapter \ref{refsection:\therefsection}}}
\addbibresource{...}
\begin{document}
\chapter{...}
\begin{refsection}
...
\end{refsection}
...
\end{refsection}
...
\end{refsection}
\htilde{...}
\begin{refsection}
\htilde{...}
\htilde{...}
\htilde{...}
\htilde{...}
\end{refsection}
\htilde{...}
\end{refsection}
\htilde{...}
\end{refsection}
\printbibheading
```

```
\printbibliography[section=1,heading=subbibliography]
\printbibliography[section=2,heading=subbibliography]
\end{document}
```

Note the definition of the bibliography heading in the above example. This is the definition taking care of the subheadings in the bibliography. The main heading is generated with a plain \chapter command in this case. The Biblatex package automatically sets a label at the beginning of every refsection environment, using the standard \label command. The identifier used is the string refsection: followed by the number of the respective refsection environment. The number of the current section is accessible via the refsection counter. When using the section option of \printbibliography, this counter is also set locally. This means that you may use the counter in heading definitions to print subheadings like "References for Chapter 3", as shown above. You could also use the title of the respective chapter as a subheading by loading the nameref package and using \nameref instead of \ref:

```
\usepackage{nameref}
\defbibheading{subbibliography}{%
  \section*{\nameref{refsection:\therefsection}}}
```

Since giving one \printbibliography command for each part of a subdivided bibliography is tedious, Biblatex provides a shorthand. The \bibbysection command automatically loops over all reference sections. This is equivalent to giving one \printbibliography command for every section but has the additional benefit of automatically skipping sections without references. In the example above, the bibliography would then be generated as follows:

```
\printbibheading
\bibbysection[heading=subbibliography]
```

When using a format with one cumulative bibliography subdivided by chapter (or any other document division) it may be more appropriate to use refsegment rather than refsection environments. The difference is that the refsection environment generates labels local to the environment while refsegment does not affect the generation of labels, hence they will be unique across the entire document. Note that when using BibTeX as the backend, refsegment environments do not require additional aux files. The next example could also be given in § 3.11.4 because, visually, it creates one global bibliography subdivided into multiple segments.

```
\documentclass{...}
\usepackage{biblatex}
\defbibheading{subbibliography}{%
  \section*{References for Chapter \ref{refsegment:\therefsection\therefsegm}
\addbibresource{...}
```

```
\begin{document}
\chapter{...}
\begin{refsegment}
...
\end{refsegment}
\chapter{...}
\begin{refsegment}
...
\end{refsegment}
...
\end{refsegment}
\printbibheading
\printbibliography[segment=1, heading=subbibliography]
\printbibliography[segment=2, heading=subbibliography]
\end{document}
```

The use of refsegment is similar to refsection and there is also a corresponding segment option for \printbibliography. The Biblatex package automatically sets a label at the beginning of every refsegment environment using the string refsegment: followed by the number of the respective refsegment environment as an identifier. There is a matching refsegment counter which may be used in heading definitions, as shown above. As with reference sections, there is also a shorthand command which automatically loops over all reference segments:

```
\printbibheading
\bibbysegment[heading=subbibliography]
```

This is equivalent to giving one \printbibliography command for every segment in the current refsection.

# 3.11.4 子参考文献表 Subdivided Bibliographies

It is very common to subdivide a bibliography by certain criteria. For example, you may want to list printed and online resources separately or divide a bibliography into primary and secondary sources. The former case is straightforward because you can use the entry type as a criterion for the type and nottype filters of \printbibliography. The next example also demonstrates how to generate matching subheadings for the two parts of the bibliography.

```
\documentclass{...}
\usepackage{biblatex}
\addbibresource{...}
\begin{document}
...
\printbibheading
\printbibliography[nottype=online, heading=subbibliography,
```

You may also use more than two subdivisions:

```
\printbibliography[type=article,...]
\printbibliography[type=book,...]
\printbibliography[nottype=article,nottype=book,...]
```

It is even possible to give a chain of different types of filters:

```
\printbibliography[section=2, type=book, keyword=abc, notkeyword=xyz]
```

This would print all works cited in reference section 2 whose entry type is @book and whose keywords field includes the keyword 'abc' but not 'xyz'. When using bibliography filters in conjunction with a numeric style, see § 3.12.5. If you need complex filters with conditional expressions, use the filter option in conjunction with a custom filter defined with \defbibfilter. See § 3.6.10 for details on custom filters.

Dividing a bibliography into primary and secondary sources is possible with a keyword filter, as shown in the above example. In this case, with only two subdivisions, it would be sufficient to use one keyword as filter criterion:

```
\printbibliography[keyword=primary,...]
\printbibliography[notkeyword=primary,...]
```

Since Biblatex has no way of knowing if an item in the bibliography is considered to be primary or secondary literature, we need to supply the bibliography filter with the required data by adding a keywords field to each entry in the bib file. These keywords may then be used as targets for the keyword and notkeyword filters, as

shown above. It may be a good idea to add such keywords right away while building a bib file.

```
@Book{key,
   keywords = {primary, some, other, keywords},
```

An alternative way of subdividing the list of references are bibliography categories. They differ from the keywords-based approach shown in the example above in that they work on the document level and do not require any changes to the bib file.

In this case it would also be sufficient to use one category only:

```
\printbibliography[category=primary,...]
\printbibliography[notcategory=primary,...]
```

It is still a good idea to declare all categories used in the bibliography explicitly because there is a \bibbycategory command which automatically loops over all categories. This is equivalent to giving one \printbibliography command for every category, in the order in which they were declared.

```
\documentclass{...}
\usepackage{biblatex}
\DeclareBibliographyCategory{primary}
\DeclareBibliographyCategory{secondary}
\addtocategory{primary}{key1, key3, key6}
\addtocategory{secondary}{key2, key4, key5}
\defbibheading{primary}{\section*{Primary Sources}}
```

```
\defbibheading{secondary}{\section*{Secondary Sources}}
\addbibresource{...}
\begin{document}
...
\printbibheading
\bibbycategory
\end{document}
```

The handling of the headings is different from \bibbysection and \bibbysegment in this case. \bibbycategory uses the name of the current category as a heading name. This is equivalent to passing heading=\category\ to \printbibliography and implies that you need to provide a matching heading for every category.

# 3.11.5 条目集 Entry Sets

An entry set is a group of entries which are cited as a single reference and listed as a single item in the bibliography. The individual entries in the set are separated by \entrysetpunct (§ 4.10.1). The Biblatex package supports two types of entry sets. Static entry sets are defined in the bib file like any other entry. Dynamic entry sets are defined with \defbibentryset (§ 3.6.12) on a per-document/per-refsection basis in the document preamble or the document body. This section deals with the definition of entry sets; style authors should also see § 4.11.1 for further information.

**3.11.5.1 Static entry sets** Static entry sets are defined in the bib file like any other entry. When using Biber as the backend, defining an entry set is as simple as adding an entry of type @set. The entry has an entryset field defining the members of the set as a separated list of entry keys:

Biber only

```
@Set{set1,
  entryset = {key1, key2, key3},
}
```

Entries may be part of a set in one document/refsection and stand-alone references in another one, depending on the presence of the @set entry. If the @set entry is cited, the set members are grouped automatically. If not, they will work like any regular entry.

When using BibTeX as the backend, which has no native support for entry sets, setting up entry sets involves more work. BibTeX requires entryset and crossref fields to be used in a special way. The members of the set are given in the entryset field of the @set entry. The @set entry also requires a crossref field which points to the first key in the entryset field. In addition to that, all members of the set require entryset fields which are reverse pointers to the entry key of the @set head entry:

```
@Set{set1,
  entryset = \{\text{key1}, \text{key2}, \text{key3}\},
  crossref = \{key1\},
}
@Article { key1,
  entryset = {set1},
  author = \{\ldots\},
  title = \{\ldots\},
  . . .
}
@InCollection{key2,
  entryset = {set1},
  author = \{\ldots\},
  title = \{\ldots\},
  . . .
}
@Article { key3,
  entryset = {set1},
  author = \{\ldots\},
  title
            = \{\ldots\},
}
```

Note that citing any set member will automatically load the entire set with BibTeX. If you want to refer to an item as part of a set in one document/refsection and as a stand-alone reference in another one, you need two distinct entries with BibTeX.

**3.11.5.2 Dynamic entry sets** Dynamic entry sets are set up and work much like static ones. The main difference is that they are defined in the document preamble or on the fly in the document body using the \defbibentryset command from § 3.6.12:

```
\defbibentryset{set1}{key1,key2,key3}
```

Dynamic entry sets in the document body are local to the enclosing refsection environment, if any. Otherwise, they are assigned to reference section 0. Those defined in the preamble are assigned to reference section 0. Note that dynamic entry sets require Biber. They will not work with any other backend.

### 3.11.6 数据容器 Data Containers

Biber only

Biber only

The @xdata entry type serves as a data container holding one or more fields. These fields may be inherited by other entries using the xdata field. @xdata entries may not be cited or added to the bibliography, they only serve as a data source for other

entries. This data inheritance mechanism is useful for fixed field combinations such as publisher/location and for other frequently used data:

```
@XData{hup,
  publisher = {Harvard University Press},
  location = {Cambridge, Mass.},
}
@Book{...,
  author = {...},
  title = {...},
  date = {...},
  xdata = {hup},
}
```

Using a separated list of keys in its xdata field, an entry may inherit data from several @xdata entries. Cascading @xdata entries are supported as well, i. e., an @xdata entry may reference one or more other @xdata entries:

```
@XData{macmillan:name,
  publisher = {Macmillan},

}
```

See also §§ 2.1.1 and 2.2.3.

# 3.11.7 电子出版信息 Electronic Publishing Information

The Biblatex package provides three fields for electronic publishing information: eprint, eprinttype, and eprintclass. The eprint field is a verbatim field similar to doi which holds the identifier of the item. The eprinttype field holds the resource name, i.e., the name of the site or electronic archive. The optional eprintclass field is intended for additional information specific to the resource indicated by the eprinttype field. This could be a section, a path, classification information, etc. If the eprinttype field is available, the standard styles will use it as

a literal label. In the following example, they would print "Resource: identifier" rather than the generic "eprint: identifier":

```
eprint = {identifier},
eprinttype = {Resource},
```

The standard styles feature dedicated support for a few online archives. For arXiv references, put the identifier in the eprint field and the string arxiv in the eprinttype field:

```
eprint = {math/0307200v3},
eprinttype = {arxiv},
```

For papers which use the new identifier scheme (April 2007 and later) add the primary classification in the eprintclass field:

```
eprint = {1008.2849v1},
eprinttype = {arxiv},
eprintclass = {cs.DS},
```

There are two aliases which ease the integration of arXiv entries. archiveprefix is treated as an alias for eprinttype; primaryclass is an alias for eprintclass. If hyperlinks are enabled, the eprint identifier will be transformed into a link to arxiv. org. See the package option arxiv in § 3.1.2.1 for further details.

For jstor references, put the stable jstor number in the eprint field and the string jstor in the eprinttype field:

```
eprint = {number},
eprinttype = {jstor},
```

When using JSTOR's export feature to export citations in BibTeX format, JSTOR uses the url field by default (where the  $\langle number \rangle$  is a unique and stable identifier):

```
url = {http://www.jstor.org/stable/number},
```

While this will work as expected, full urls tend to clutter the bibliography. With the eprint fields, the standard styles will use the more readable "JSTOR:  $\langle number \rangle$ " format which also supports hyperlinks. The  $\langle number \rangle$  becomes a clickable link if hyperref support is enabled.

For PubMed references, put the stable PubMed identifier in the eprint field and the string pubmed in the eprinttype field. This means that:

```
url = {http://www.ncbi.nlm.nih.gov/pubmed/pmid},
becomes:
eprint = {pmid},
eprinttype = {pubmed},
```

and the standard styles will print "PMID:  $\langle pmid \rangle$ " instead of the lengthy URL. If hyperref support is enabled, the  $\langle pmid \rangle$  will be a clickable link to PubMed.

For handles (HDLs), put the handle in the eprint field and the string hdl in the eprinttype field:

```
eprint = {handle},
eprinttype = {hdl},
```

For Google Books references, put Google's identifier in the eprint field and the string googlebooks in the eprinttype field. This means that, for example:

```
url = {http://books.google.com/books?id=XXu4AkRVBBoC},
```

would become:

```
eprint = {XXu4AkRVBBoC},
eprinttype = {googlebooks},
```

and the standard styles would print "Google Books: XXu4AkRVBBoC" instead of the full URL. If hyperref support is enabled, the identifier will be a clickable link to Google Books.<sup>23</sup>

Note that eprint is a verbatim field. Always give the identifier in its unmodified form. For example, there is no need to replace \_ with \\_. Also see § 4.11.2 on how to add dedicated support for other eprint resources.

### 3.11.8 额外的摘要和注释 External Abstracts and Annotations

Styles which print the fields abstract and/or annotation may support an alternative way of adding abstracts or annotations to the bibliography. Instead of including the text in the bib file, it may also be stored in an external LaTeX file. For example, instead of saying

```
@Article{key1,
    ...
    abstract = {This is an abstract of entry 'key1'.}
}
```

in the bib file, you may create a file named bibabstract-key1.tex and put the abstract in this file:

```
This is an abstract of entry 'key1'.
```

<sup>&</sup>lt;sup>23</sup>Note that the Google Books ID seems to be a bit of an 'internal' value. As of this writing, there does not seem to be any way to search for an ID on Google Books. You may prefer to use the url in this case.

The name of the external file must be the entry key prefixed with bibabstract-or bibannotation—, respectively. You can change these prefixes by redefining \bibabstractprefix and \bibannotationprefix. Note that this feature needs to be enabled explicitly by setting the package option loadfiles from § 3.1.2.1. The option is disabled by default for performance reasons. Also note that any abstract and annotation fields in the bib file take precedence over the external files. Using external files is strongly recommended if you have long abstracts or a lot of annotations since this may increase memory requirements significantly. It is also more convenient to edit the text in a dedicated LaTeX file. Style authors should see § 4.11.3 for further information.

# 3.12 提示与警告 Hints and Caveats

This section provides additional usage hints and addresses some common problems and potential misconceptions.

# 3.12.1 与KOMA-Script 类共用的方法 Usage with KOMA-Script Classes

When using Biblatex in conjunction with one of the scrbook, scrreprt, or scrartcl classes, the headings bibliography and biblist from § 3.6.8 are responsive to the bibliography-related options of these classes. You can override the default headings by using the heading option of \printbibliography, \printbibheading and \printbiblist. See §§ 3.6.2, 3.6.4, 3.6.8 for details. All default headings are adapted at load-time such that they blend with the behavior of these classes. If one of the above classes is detected, Biblatex will also provide the following additional tests which may be useful in custom heading definitions:

#### \ifkomabibtotoc{ $\langle true \rangle$ } { $\langle false \rangle$ }

Expands to  $\langle true \rangle$  if the class would add the bibliography to the table of contents, and to  $\langle false \rangle$  otherwise.

### 

Expands to  $\langle true \rangle$  if the class would add the bibliography to the table of contents as a numbered section, and to  $\langle false \rangle$  otherwise. If this test yields  $\langle true \rangle$ ,  $\land$  if komabibtotoc will always yield  $\langle true \rangle$  as well, but not vice versa.

# 3.12.2 与 Memoir 类共用的方法 Usage with the Memoir Class

When using Biblatex with the memoir class, most class facilities for adapting the bibliography have no effect. Use the corresponding facilities of this package instead (§§ 3.6.2,

<sup>&</sup>lt;sup>24</sup>This applies to the traditional syntax of these options (bibtotoc and bibtotocnumbered) as well as to the ⟨key⟩= ⟨value⟩ syntax introduced in кома-Script 3.x, i.e., to bibliography=nottotoc, bibliography=totoc, and bibliography=totocnumbered. The global toc=bibliography and toc=bibliographynumbered options as well as their aliases are detected as well. In any case, the options must be set globally in the optional argument to \documentclass.

3.6.8, 3.6.9). Instead of redefining memoir's \bibsection, use the heading option of \printbibliography and \defbibheading (§§ 3.6.2 and 3.6.8). Instead of \prebibhook and \postbibhook, use the prenote and postnote options of \printbibliography and \defbibnote (§§ 3.6.2 and 3.6.9). All default headings are adapted at load-time such that they blend well with the default layout of this class. The default headings bibliography and biblist (§ 3.6.8) are also responsive to memoir's \biblintoc and \nobibintoc switches. The length register \biblitemsep is used by Biblatex in a way similar to memoir (§ 3.9.3). This section also introduces some additional length registers which correspond to memoir's \biblistextra. Lastly, \setbiblabel does not map to a single facility of the Biblatex package since the style of all labels in the bibliography is controlled by the bibliography style. See § 4.2.2 in the author section of this manual for details. If the memoir class is detected, Biblatex will also provide the following additional test which may be useful in custom heading definitions:

```
\infty \iff if memoir bibintoc {\langle true \rangle } {\langle false \rangle }
```

Expands to  $\langle true \rangle$  or  $\langle false \rangle$ , depending on memoir's \bibintoc and \nobibintoc switches. This is a LaTeX frontend to memoir's \ifnobibintoc test. Note that the logic of the test is reversed.

### 3.12.3 标注中的页码 Page Numbers in Citations

If the  $\langle postnote \rangle$  argument to a citation command is a page number or page range, Biblatex will automatically prefix it with 'p.' or 'pp.' by default. This works reliably in typical cases, but sometimes manual intervention may be required. In this case, it is important to understand how this argument is handled in detail. First, Biblatex checks if the postnote is an Arabic or Roman numeral (case insensitive). If this test succeeds, the postnote is considered as a single page or other number which will be prefixed with 'p.' or some other string which depends on the pagination field (see § 2.3.10). If it fails, a second test is performed to find out if the postnote is a range or a list of Arabic or Roman numerals. If this test succeeds, the postnote will be prefixed with 'pp.' or some other string in the plural form. If it fails as well, the postnote is printed as is. Note that both tests expand the  $\langle postnote \rangle$ . All commands used in this argument must therefore be robust or prefixed with \protect. Here are a few examples of  $\langle postnote \rangle$  arguments which will be correctly recognized as a single number, a range of numbers, or a list of numbers, respectively:

```
\cite[25]{key}
\cite[vii]{key}
\cite[XIV]{key}
\cite[34--38]{key}
\cite[iv--x]{key}
\cite[185/86]{key}
\cite[XI \& XV]{key}
```

```
\cite[3, 5, 7]{key}
\cite[vii--x; 5, 7]{key}
```

In some other cases, however, the tests may get it wrong and you need to resort to the auxiliary commands \pno, \ppno, and \nopp from § 3.7.8. For example, suppose a work is cited by a special pagination scheme consisting of numbers and letters. In this scheme, the string '27a' would mean 'page 27, part a'. Since this string does not look like a number or a range to Biblatex, you need to force the prefix for a single number manually:

```
\cite[\pno~27a]{key}
```

There is also a \ppno command which forces a range prefix as well as a \nopp command which suppresses all prefixes:

```
\cite[\ppno~27a--28c]{key}
\cite[\nopp 25]{key}
```

These commands may be used anywhere in the  $\langle postnote \rangle$  argument. They may also be used multiple times. For example, when citing by volume and page number, you may want to suppress the prefix at the beginning of the postnote and add it in the middle of the string:

```
\cite[VII, \pno~5]{key}
\cite[VII, \pno~3, \ppno~40--45]{key}
\cite[see][\ppno~37--46, in particular \pno~40]{key}
```

There are also two auxiliary command for suffixes like 'the following page(s)'. Instead of inserting such suffixes literally (which would require \ppno to force a prefix):

```
\cite[\ppno~27~sq.]{key}
\cite[\ppno~55~sqq.]{key}
```

use the auxiliary commands \psq and \psqq. Note that there is no space between the number and the command. This space will be inserted automatically and may be modified by redefining the macro \sqspace.

```
\cite[27\psq] {key}
\cite[55\psqq] {key}
```

Since the postnote is printed without any prefix if it includes any character which is not an Arabic or Roman numeral, you may also type the prefix manually:

```
\text{cite}[p.~5]\{\text{key}\}
```

It is possible to suppress the prefix on a per-entry basis by setting the pagination field of an entry to 'none', see § 2.3.10 for details. If you do not want any prefixes at all or prefer to type them manually, you can also disable the entire mechanism in the document preamble or the configuration file as follows:

```
\DeclareFieldFormat{postnote}{#1}
```

The  $\langle postnote \rangle$  argument is handled as a field and the formatting of this field is controlled by a field formatting directive which may be freely redefined. The above definition will simply print the postnote as is. See §§ 4.3.2 and 4.4.2 in the author guide for further details.

# 3.12.4 姓名组成部分及其间距 Name Parts and Name Spacing

The Biblatex package gives users and style authors very fine-grained control of name spacing and the line-breaking behavior of names, especially when they are using Biber as the backend. The commands discussed in the following are documented in §§ 3.9.1 and 4.10.1. This section is meant to give an overview of how they are put together. A note on terminology: a name *part* is a basic part of the name, for example the first or the last name. Each part of a name may be a single name or it may be composed of multiple names. For example, the name part 'first name' may be composed of a first and a middle name. The latter are referred to as name *elements* in this section. Let's consider a simple name first: "John Edward Doe". This name is composed of the following parts:

First John Edward
Prefix —
Last Doe
Suffix —

The spacing, punctuation and line-breaking behavior of names is controlled by six macros:

 $a = \bibnamedelima$ Inserted by the backend after the first element of every name part if that element is less than three characters long and before the last element of every name part. b=\bibnamedelimb Inserted by the backend between all elements of a name part where \bibnamedelima does not apply. c=\bibnamedelimc Inserted by a formatting directive between the name prefix and the last name if useprefix=true. If useprefix=false, \bibnamedelimd is used instead.  $d=\bibnamedelimd$ Inserted by a formatting directive between name parts where \bibnamedelimc does not apply.  $i = \bibnamedelimi$ Replaces \bibnamedelima/b after initials p=\revsdnamepunct Inserted by a formatting directive after the last name when the name parts are reversed.

This is how the delimiters are employed:

Initials in the bib file get a special delimiter:

Let's consider a more complex name: "Charles-Jean Étienne Gustave Nicolas de La Vallée Poussin". This name is composed of the following parts:

First Charles-Jean Étienne Gustave Nicolas

Prefix de

Last La Vallée Poussin

Suffix -

The delimiters:

 $\texttt{Charles-Jean}\big|_{\mathtt{b}} \texttt{Étienne}\big|_{\mathtt{b}} \texttt{Gustave}\big|_{\mathtt{a}} \texttt{Nicolas}\big|_{\mathtt{d}} \texttt{de}\big|_{\mathtt{c}} \texttt{La}\big|_{\mathtt{a}} \texttt{Vall\acute{e}e}\big|_{\mathtt{a}} \texttt{Poussin}$ 

Note that \bibnamedelima/b/i are inserted by the backend. The backend processes the name parts and takes care of the delimiters between the elements that make up a name part, processing each part individually. In contrast to that, the delimiters between the parts of the complete name (\bibnamedelimc/d) are added by name formatting directives at a later point in the processing chain. The spacing and punctuation of initials is also handled by the backend and may be customized by redefining the following three macros:

b=\bibinitdelim Inserted by the backend between multiple initials.

 $\label{lem:condition} \textbf{c=} \\ \textbf{bibinithyphendelim} \quad \textbf{Inserted by the backend between the initials of} \\$ 

hyphenated name parts, replacing

\bibinitperiod and \bibinitdelim.

This is how they are employed:

J|.| E|. Doe

K.-H. Mustermann

# 3.12.5 参考文献筛选器和标注标签 Bibliography Filters and Citation Labels

The citation labels generated by this package are assigned to the full list of references before it is split up by any bibliography filters. They are guaranteed to be unique across the entire document (or a refsection environment), no matter how many bibliography filters you are using. When using a numeric citation scheme, however, this will most likely lead to discontinuous numbering in split bibliographies. Use the defernumbers package option to avoid this problem. If this option is enabled, numeric labels are assigned the first time an entry is printed in any bibliography.

# 3.12.6 **参考文献标题中的活动字符** Active Characters in Bibliography Headings

Packages using active characters, such as babel, polyglossia, csquotes, or underscore, usually do not make them active until the beginning of the document body to avoid interference with other packages. A typical example of such an active character is the Ascii quote ", which is used by various language modules of the babel/polyglossia packages. If shorthands such as "< and "a are used in the argument to \defbibheading and the headings are defined in the document preamble, the non-active form of the characters is saved in the heading definition. When the heading is typeset, they do not function as a command but are simply printed literally. The most straightforward solution consists in moving \defbibheading after \begin{document}. Alternatively, you may use babel's \shorthandon and \shorthandoff commands to temporarily make the shorthands active in the preamble. The above also applies to bibliography notes and the \defbibnote command.

# 3.12.7 在参考文献分节和分部中的编组 Grouping in Reference Sections and Segments

All LaTeX environments enclosed in \begin and \end form a group. This may have undesirable side effects if the environment contains anything that does not expect to be used within a group. This issue is not specific to refsection and refsegment environments, but it obviously applies to them as well. Since these environments will usually enclose much larger portions of the document than a typical itemize or similar environment, they are simply more likely to trigger problems related to grouping. If you observe any malfunctions after adding refsection environments to a document (for example, if anything seems to be 'trapped' inside the environment), try the following syntax instead:

```
\chapter{...}
\refsection
...
\endrefsection
```

This will not from a group, but otherwise works as usual. As far as Biblatex is concerned, it does not matter which syntax you use. The alternative syntax is also supported by the refsegment environment. Note that the commands \newrefsection and \newrefsegment do not form a group. See §§ 3.6.5 and 3.6.6 for details.

# 4 样式作者指南

手册的这一部分介绍 Biblatex 包的作者接口。该指南包括了编写参考文献表和引用样式或本地化模型所需知晓的所有内容。在阅读本部分前最好先阅读用户指南。

## 4.1 概述

在讨论 Biblatex 提供的命令和工具之前,我们将首先介绍一些基本概念。Biblatex 包以一种特殊的方式使用辅助文件。最值得注意的是当使用 BibTeX 后端时,bbl文件的使用方式是有区别的,只有一个bst文件可用来实现结构化的数据接口,而不是输出可打印的数据。使用 LaTeX 的标准参考文献工具,一个文档通常包括任意数量的文献引用命令,以及常放在文档最后的\bibliographystyle和\bibliography命令。文献引用命令在文档中的位置是任意的,而\bibliographystyle和\bibliography命令则标记了打印参考文献表的位置,比如:

```
\documentclass{...}
\begin{document}
\cite{...}
...
\bibliographystyle{...}
\bibliography{...}
\end{document}
```

处理这些文件存在一定的流程,其过程如下:

- 1. 运行 latex: 第一次运行latex, \bibstyle和 \bibdata命令,以及所有引用的命令\citation写入到aux文件中。在这个时候,各引文标注<sup>25</sup>是未定义的,因为 LaTeX 等待 BibTeX 提供需要的数据,当然参考文献表也不存在。
- 2. 运行 bibtex:BibTeX 在bbl文件中写入一个thebibliography环境,提供aux文件中\citation命令所需求所有条目,这些条目数据来自bib文件。
- 3. 运 行latex, 第 二 次 运 行latex,thebibliography环 境 中的\bibitem命令在aux文件中为每个参考文献条目写入\bibcite命令。这些\bibcite命令定义的标签将用于\cite命令。然而,各引文标注仍然未定义,因为这些标签在最后一次运行latex前仍未得到。
- 4. 运行latex: 第三次运行,这时引用的标签已经定义因为在导言区最后读入了aux文件。这样所有的标注可以正确打印出来。

注意到所有的参考文献数据都以最终格式 (指最后打印出的格式) 写入bb1文件。该文件的读取和处理如同任何文档中的可打印章节。比如,考虑在一个bib文件中有如下条目:

@Book{companion,

author = {Michel Goossens and Frank Mittelbach and Alexander Samarin},

<sup>&</sup>lt;sup>25</sup>这里的 references 译为引文标注,指在引用命令导致在正文中出现的标注,这个标注由标签 label 构成。

```
title = {The LaTeX Companion},
publisher = {Addison-Wesley},
address = {Reading, Mass.},
year = {1994},
}
```

根据plain.bst 样式, BibTeX 在bbl文件中输出该条目如下:

```
\bibitem{companion}
Michel Goossens, Frank Mittelbach, and Alexander Samarin.
\newblock {\em The LaTeX Companion}.
```

\newblock Addison-Wesley, Reading, Mass., 1994.

默认情况下,LaTeX 生成顺序制引用标签,因此\bibitem命令在aux文件中写入的行,如下:

\bibcite{companion}{1}

要实现一个不同的引用标签样式,意味着需要通过aux文件传递更多的数据。 比如,当使用natbib包时,aux文件包含的引用信息行,如下:

 $\begin{array}{ll} \bibcite{companion}{\{1\}\{1994\}\{\{Goossens\ et~al.\}\}\{\{Goossens,\ Mittelbach,\ and\ Samarin\}\}\} \end{array}$ 

Biblatex 包支持任何格式的引用标签,因此引用命令需要访问所有的参考文献数据。只要看一看同样需要在引用中提供所有参考文献数据的jurabib包的输出,我们就可以明白到这对上述处理过程来说意味着什么。

```
\bibcite{companion}{{Goossens\jbbfsasep Mittelbach\jbbstasep Samarin}%
   {}{{0}{}{book}{1994}{}{}{}{Reading, Mass.\bpubaddr{}Addison-Wesley%
   \bibbdsep{} 1994}}{{The LaTeX Companion}{}{}{}{}{}{}{}{}bibnf
   {Goossens}{Michel}{M.}{}{}Bibbfsasep\bibnf{Mittelbach}{Frank}{F.}%
   {}{}\Bibbstasep\bibnf{Samarin}{Alexander}{A.}{}}{\bibtfont{The
   LaTeX Companion}.\ \apyformat{Reading, Mass.\bpubaddr{}
   Addison-Wesley\bibbdsep{} 1994}}}
```

这种情况下,整个thebibliography环境的内容通过aux文件有效传递。数据从bbl文件中读取出来,写入到aux中,再从aux读出保存到内存中。而参考文献表本身的生成仍然需要读入bbl文件。如果采用这种方式,Biblatex包将被迫通过aux文件回收所有的数据。但上述这个处理过程过度且多余,因为不管怎么样,数据都需要保存在内存中。

这种传统的处理过程是基于一个假设,即条目的完整数据只是参考文献表需要而所有的引用标注都使用短标签。这对于有内存限制的情况是非常有效的,但也意味着很难扩展。这就是 Biblatex 采取另一种不同方法的原因。首先,文档结构略有变化。取消在文档内使用\bibliography命令,数据库文件由导言区的\addbibresource命令指定,完全忽略\bibliographystyle命令(而所有的功能都有包选项控制),参考文献表使用\printbibliography命令打印:

```
\documentclass{...}
\usepackage[...] {biblatex}
\addbibresource{...}
\begin{document}
\cite{...}
...
\printbibliography
\end{document}
```

为了简化整个流程,Biblatex 基本上以应用aux文件的方式应用bbl文件,并舍弃了\bibcite命令。于是,我们得到如下流程:

- 1. 运行latex: 第一步类似于上述的传统方式:\bibstyle 和 \bibdata以及所有引用的\citation命令写入到aux文件中(以 BibTeX 为后端)或者写到bcf文件中(以 Biber 为后端)。然后等待后端提供需要的数据。当以 BibTeX 为后端时,Biblatex 使用一个特殊 bst的文件,该文件用于实现 BibTeX 后端的数据接口,因此\bibstyle命令则必须是\bibstyle{biblatex}。
- 2. 运行biber 或 bibtex: 后端提供了辅助文件中所有\citation命令所需的条目,这些条目的数据来自bib文件。然而,它并不在bbl文件中写出一个可打印的参考文献表,而是一个参考文献的结构化表达数据。类似于aux文件,读入该bbl文件时不打印任何东西,仅是将数据存入内存中。
- 3. 运行latex: 第二次运行, bbl文件在文档正文开始的时候处理, 类似于aux文件。从这开始, 所有参考文献数据都已在内存中, 所以所有的引用都可以正确打印。<sup>26</sup> 引用命令不仅可以访问预定义的标签, 还可以访问完整的参考文献数据。参考文献表由内存中的相同数据生成, 可以根据需要进行筛选和划分。

我们再次考虑上面给出的条目样例:

@Book{companion,

```
author = {Michel Goossens and Frank Mittelbach and Alexander Samarin},
title = {The LaTeX Companion},
publisher = {Addison-Wesley},
address = {Reading, Mass.},
year = {1994},
```

使用 Biblatex 及 Biber 后端,这一条目实际上以如下格式输出:

<sup>&</sup>lt;sup>26</sup>如果defernumbers 包选项打开,Biblatex 以类似于传统过程的一种算法来生成顺序制标签。这种情况下,这些数字在参考文献表打印的时候指定且需从后端辅助文件中回收。因此需要额外运行一次 LaTeX 以在标注中获得它们。

```
\entry{companion}{book}{}
  \labelname{author}{3}{}{%
    {{uniquename=0,hash=...}{Goossens}{G.}{Michel}{M.}{}{}{}}}%
    {{uniquename=0, hash=...}{Mittelbach}{M.}{Frank}{F.}{}{}{}}}}%
    {{uniquename=0,hash=...}{Samarin}{S.}{Alexander}{A.}{}{}{}{}}}%
  }
 \name{author}{3}{}{%
    {{uniquename=0, hash=...}{Goossens}{G.}{Michel}{M.}{}{}{}}}}
    {{uniquename=0, hash=...}{Mittelbach}{M.}{Frank}{F.}{}{}{}}}%
    {{uniquename=0,hash=...}{Samarin}{S.}{Alexander}{A.}{}{}{}{}}}
  \list{publisher}{1}{%
    {Addison-Wesley}%
  \list{location}{1}{%
    {Reading, Mass.}%
 \field{title}{The LaTeX Companion}
 \field{year}{1994}
\endentry
```

由这一例子可见,某种程度上说结构化的数据构成了bb1文件内容<sup>27</sup>。从这点上说,没有任何关于参考文献条目最终格式的决定。而参考文献表和引用标注的格式化由LaTeX宏控制,这些宏定义在参考文献和引用样式文件中。

# 4.2 参考文献样式

一个参考文献样式是用于控制打印参考文献表中条目的宏的集合,定义在扩展名为bbx的文件中。Biblatex包在其结尾加载所选择的参考文献样式文件。需要注意:一些由多个标准样式文件共享的常用宏定义在biblatex.def文件中。该文件同样在包结尾加载,但先于参考文献样式文件。

# 4.2.1 参考文献样式文件 Bibliography Style Files

在我们讨论参考文献样式的各部分之前,考虑一个典型的bbx文件总体结构,如下:

```
\ProvidesFile{example.bbx}[2006/03/15 v1.0 biblatex bibliography style]
\defbibenvironment{bibliography}
{...}
{...}
```

149

<sup>&</sup>lt;sup>27</sup>这里应该是 bbl 文件而不是原文的 bib 文件

```
\defbibenvironment{shorthand}
    {...}
    {...}
    {...}
\InitializeBibliographyStyle{...}
\DeclareBibliographyDriver{article}{...}
\DeclareBibliographyDriver{book}{...}
\DeclareBibliographyDriver{inbook}{...}
...
\DeclareBibliographyDriver{shorthand}{...}
\endinput
```

参考文献样式文件的主要结构包含如下命令:

## \RequireBibliographyStyle{\langle style \rangle}

该命令是可选的,用于指定一些建立在更一般的参考文献样式上的特殊样式。该命令加载样式文件style.bbx。

#### $\InitializeBibliographyStyle{\langle code\rangle}$

该命令在参考文献表开始之前插入任意给定的〈code〉,但在参考文献表所形成的 组内。该命令是可选的。它对于不同的参考文献驱动共享一些定义是有用的,但 不能用于参考文献组外。记住,文档中可以有多个参考文献表,如果参考文献驱 动进行了任何全局设置,应在下一个参考文献开始前重设<sup>28</sup>。

## $\DeclareBibliographyDriver{\langle entrytype \rangle} {\langle code \rangle}$

定义一个参考文献驱动。一个驱动'driver'是一个宏用于控制某一具体的参考文献条目(当打印参考文献表的时候)或者某一具体命名了的参考文献表(当打印多个参考文献表的时候)。〈entrytype〉与bib文件中使用的条目类型对应,以小写字母给出(见§2.1)。〈entrytype〉变量可以是一个星号。这种情况下,该驱动退化为没有具体驱动的条目类型。〈code〉是任意代码用于打印各自〈entrytype〉的参考文献条目。该命令是必须的。每个参考文献样式都应提供所用到的每类条目的驱动。

#### \DeclareBibliographyAlias {\langle alias \rangle \langle entrytype \rangle \rangle}

如果一个参考文献驱动用于处理多个参考文献条目类型,该命令可以用来定义某类已经定义驱动的〈entrytype〉别名。〈alias〉选项可以是一个星号,这种情况下,该驱动用于那些没有指定驱动的参考文献条目。

## $\DeclareBibliographyOption{\langle key \rangle} [\langle value \rangle] {\langle code \rangle}$

该命令以 $\langle key \rangle$ = $\langle value \rangle$ 格式定义额外的导言区选项。 $\langle key \rangle$ 是选项键名。 $\langle code \rangle$ 是任意 TeX 代码用于该选项使用时执行。传递给选项的 value 值作为 $\langle code \rangle$ 的输入参数#1。可选的 $\langle value \rangle$ 是没有给定任何输入参数时使用的默认参数。这对于布尔开关是有用的,比如,某一选项定义如下:

<sup>28</sup>这里不是很理解

```
\DeclareBibliographyOption{somekey}[true]{...}
```

当无键值给出时,该'somekey'等价于'somekey=true'。

```
\DeclareEntryOption\{\langle key \rangle\}\ [\langle value \rangle]\ \{\langle code \rangle\}
```

类似于\DeclareBibliographyOption,但用于定义一些条目的可设选项,这些选项在§2.2.3节中的options域中。(code)在Biblatex 为一个引用命令或参考文献驱动准备条目数据时执行。

# 4.2.2 参考文献环境 Bibliography Environments

除了定义参考文献驱动,参考文献样式也要定义参考文献环境用于控制参考文献表的输出。这些环境由命令\defbibenvironment名义。默认情况下,\printbibliography使用bibliography环境。下面是一个适用于不打印标签的参考文献样式的环境定义:

```
\defbibenvironment{bibliography}
    {\list
        {}
        {\setlength{\leftmargin}{\bibhang}%
        \setlength{\itemindent}{-\leftmargin}%
        \setlength{\itemsep}{\bibitemsep}%
        \setlength{\parsep}{\bibparsep}}}
        {\endlist}
        {\item}
```

该定义使用 Biblatex 提供的\bibhang尺寸,应用了一个带悬挂缩进的list环境。它允许使用\bibitemsep 和 \bibparsep来实现一定程度的布局调整,Biblatex 提供的这两个尺寸就是为了该目的 (见 § 4.10.3)。作者年制 (authoryear) 和作者题名制 (authortitle) 的参考文献样式使用类似于该例的定义。

```
\defbibenvironment{bibliography}
{\list
    {\printfield[labelnumberwidth] {labelnumber}}
    {\setlength{\labelwidth}{\labelnumberwidth}%
    \setlength{\labelsep}{\biblabelsep}%
    \addtolength{\labelsep}{\biblabelsep}%
    \setlength{\litemsep}{\biblitemsep}}%
    \setlength{\parsep}{\biblitemsep}}%
    \setlength{\parsep}{\bibparsep}}%
    \renewcommand*{\makelabel}[1]{\hss##1}}
{\endlist}
{\item}
```

151

一些参考文献样式在参考文献列表中打印标签。比如,设计一个顺序引用格式的参考文献样式需要在参考文献表的每个条目前面打印顺序数字,这样参考文献看起来就像一个顺序列表。在第一个例子中,\list命令的第一个参数是空的。在这个例子中,我们需要在其中插入数字,这些数字由 Biblatex 的labelnumber域中的数字提供。我们也应用 Biblatex 提供的几个尺寸和工具,详见 §§ 4.10.4 and 4.10.5。顺序制 (numeric) 参考文献样式使用如上的定义。除 labelnumber 由 labelalpha 代替和 labelnumberwidth 由 labelalphawidth 代替外,顺序字母制 (alphabetic) 的样式也是类似的。

各参考文献表以相似方式处理。\printbiblist命令默认使用以 bibliography list 命名的环境 (当使用 BibTeX 时,\printshorthands总是使用 shorthand环境)。一个典型的例子如下,其中的尺寸和工具定义详见第 §§ 4.10.4 and 4.10.5节。

#### 4.2.3 参考文献驱动 Bibliography Drivers

在我们讨论 Biblatex 包的数据接口命令前,了解一下参考文献驱动的结构是有益的。注意,虽然下面给出的例子是大为简化的,但仍具有说明意义。为可读性考虑,我们忽略了一些可能是@book条目的域,并且简化处理没有忽略的域。主要是为了说明驱动的结构。关于 BibTeX 文件的格式域与 Biblatex 包的数据类型的映射信息,见 § 2.2。

```
\DeclareBibliographyDriver{book} {%
  \printnames{author}%
  \newunit\newblock
  \printfield{title}%
  \newunit\newblock
  \printlist{publisher}%
  \newunit
  \printlist{location}%
  \newunit
```

```
\printfield{year}%
\finentry}
```

标准的参考文献样式应用两个参考文献宏 begentry 和 finentry。

推荐使用这两个宏,因为方便在驱动开始或结束时使用钩子。

回到上述给出 book 条目类型的驱动,我们发现有一些缺省:即\printnames,\printlist,和\printfield命令所使用的格式命令。为了说明一个格式话指令是什么,这里给出上述驱动举例中所使用虚构指令。域的格式是直接的,域的值直接作为参数传递给格式命令,并根据需要格式化。下面的指令简单地将输入参数用一个\emph命令包裹:

```
\DeclareFieldFormat{title}{\emph{#1}}
```

列表格式则要复杂一些。在将列表划分为独立的项后,Biblatex 将对列表中的每一项执行格式化命令。各项作为参数传递给格式化命令。列表中各项间的分隔符由相应的命令控制,因此我们必须在插入分隔符前要检查是否在列表中或者是列表末尾。

\DeclareListFormat{location}{%当打印的项的序号小于最大序号说明在列表内#1%所以用逗号隔开

```
\ifthenelse{\value{listcount}<\value{liststop}}
{\addcomma\space}
{}}</pre>
```

姓名 (name) 的格式化命令类似于这种抄录列表,但列表中的单个项是姓名,因此需要自动的解析为姓名的不同组成部分。列表格式化命令对列表中每个姓名都执行一次,信吗的各个部分以分开的参数传递给该命令。比如,#1 是姓 (last name) 和#3 是名 (first name)。下面给出一个简化的格式化命令例子:

```
\DeclareNameFormat{author}{%
  \ifthenelse{\value{listcount}=1}
    {#1%
    \ifblank{#3}{}{\addcomma\space #3}}
  {\ifblank{#3}{}{#3\space}%
    #1}%
```

153

```
\ifthenelse{\value{listcount}<\value{liststop}}
    {\addcomma\space}
    {}}</pre>
```

上述各格式化命令调换了第一个作者的姓名前后顺序"Last, First"),而其余姓名则是常规顺序 ("First Last")。注意: 必须要保证提供的姓名部分是姓 (last name),因此我们必须要检查实际数据中姓名的哪些部分是存在的。如果姓名的一些部分不存在,则相关的变量就为空。如同抄录列表的命令,在各独立项之间插入的分隔符也由格式化命令控制,因为我们也要检查是否处于列表中还是在其末尾,这也是第二个\ifthenelse命令做的事情。

# 4.2.4 特殊域 Special Fields

下面的列表和域用于 Biblatex 传递数据给参考文献驱动和引用命令。它们由包自动定义,并不是用于bib文件。从参考文献和引用样式的角度,它们与bib中的域并没有什么不同。

#### 4.2.4.1 一般域 Generic Fields

#### entrykey field (string)

bib文件中某一项的 entry key。这是一个字符串,用于 Biblatex 及其后端确 定bib文件中的一个条目。

#### childentrykey field (string)

当引用一个条目集的子条目时,Biblatex 给引用数据提供了父@set条目的数据。这意味着entrykey表示的是父条目的关键词。而子条目的关键词在childentrykey域中提供。该域仅在引用一个条目集的某一子条目时使用。

# datelabelsource field (literal)

Biber only

该域决定由\DeclareLabeldate命令所选择的 date 域名的'date'的前缀词。比如,如果标签的 date 域是eventdate,那么datelabelsource将会是'event'。如果\DeclareLabeldate命令选择date域,那么datelabelsource将会定义一个空字符串。这使得datelabelsource的内容可以用于构建对\DeclareLabeldate选择的域的引用。因为\DeclareLabeldate也能选择用于备用的抄录字符串,如果datelabelsource未定义,那么要不labeldate包选项设置为 false,或是\DeclareLabeldate也由由金选择一个抄录字符串用于代替 date 域。要记住\DeclareLabeldate也用来选择非日期域作为备用,因此datelabelsource可以包含一个域名。所以,总结起来,规则是:

```
\iffieldundef{datelabelsource}
{
% labeldate package option is not set or \DeclareLabeldate resolved t
}
```

```
{
\iffieldundef{\thefield{datelabelsource}}
{
% datelabelsource contains a date field name prefix like "", "event",
}
{
% datelabelsource contains a non-date field
}
}
```

## entrytype field (string)

条目类型 (@book, @inbook, 等), 以小写字母给出。

#### childentrytype field (string)

当引用一个条目集的子条目时,Biblatex 给引用命令提供父集条目的数据。这意味着entrytype保存父条目的类型。子条目的类型则由childentrytype域提供。该域仅在引用一个条目集的子条目时使用。

### entrysetcount field (integer)

该域保存的整数用于指明一个集中某个集成员的位置 (起始值是 1)。该域仅对一个条目集的子条目有用。

#### hash field (string)

Biber only

该域非常特殊,仅在姓名格式化命令中使用。它保存一个 hash 字符串,用于唯一的确定姓名列表中的单个姓名。该信息对于姓名列表中的所有姓名都有提供。另外参见namehash和fullhash。

# namehash field (string)

一个 hash 字符串用于唯一确定labelname列表。这对再现检查很有用。比如,一个将再次出现的作者和编者用一个类似'idem'的字符串代替的引用样式,可以用\savefield命令保存namehash域,并将其用于后面\iffieldequals(见 §§ 4.6.1 and 4.6.2)命令的比较中。namehash域通过labelname列表的截短得到,即它的结果与maxnames和minnames选项相关。另外参见hash和fullhash。

#### fullhash field (string)

一个 hash 字符串用于唯一确定labelname列表。该域域namehash有两点不同:1. 产生 hash 时忽略shortauthor和shorteditor列表。2. 该 hash 指的是完整的 列表,忽略maxnames和minnames选项。另外见hash和namehash。

# pageref list (literal)

如果backref包选项打开,该域保存各被引用条目所在页的页码。如果文档中有refsection环境,反向引用是针对当前参考文献节的。

#### sortinit field (literal)

该域保存用于排序的信息首字符。使用 BibTeX 时,该域也用来代替sortinithash域。

#### sortinithash field (string)

Biber only

使用 Biber 时,该域保存排序字符串的第一个扩展字素集群 (基本上是第一个字符)的 Unicode 排序规则算法主要权重的 hash 值。当按照字母表顺序划分参考文献列表时很有用,该域有内部\bibinitsep所使用。(见 § 3.9.3)

#### clonesourcekey

field (string)

Biber only

该域保存复制条目源条目的关键词。复制条目常用于处理相关条目和related域。

#### 4.2.4.2 引用标签中使用的域

#### labelalpha field (literal)

当使用 BibTeX 为后端时,生成一个类似于传统 BibTeX 的alpha.bst 样式的标签。这一默认标签由抽取labelname列表的首字母加上出版年的最后两个数字构成。label域可用来重写它的非数值部分 (non-numeric portion)。如果定义了label域,Biblatex 将使用它的值加上出版年的后两个数字生成labelalpha。shorthand域也可用来重写整个标签。如果定义了该域,labelalpha就是shorthand域,而不是一个自动生成的标签。使用 Biber 时,用户可以定义用来构建字母顺序标签的模板(见§ 4.5.4),而默认的模板域上面 bibtex 后端使用的格式相同。一个完整的字母顺序('alphabetic')标签由以下域构成:labelalpha 加 extraalpha。注意labelalpha和 extraalpha域需要打开包选项 labelalpha(§ 3.1.2.3)。另外参见 extraalpha和 § 3.9.1的\labelalphaothers。

Biber only

#### extraalpha field (integer)

当参考文献中包含同一作者同一年出版的多个引文时,'alphabetic' 引用格式常需要一个额外的字母加入标签来区分。这种情况下extraalpha域保存一个整数可用命令 \mknumalph 转换成字母或以其他方式格式化。该域类似于在作者年 (author-year) 格式中extrayear的作用。完整的 'alphabetic' 的标签由labelalpha 加 extraalpha构成。注意labelalpha和 extraalpha域需要打开包选项 labelalpha(详见 § 3.1.2.3)。另外参见 labelalpha和§ 3.9.1的\labelalphaothers。表5总结了不同的extra\*非歧义计数器和他们追踪的信息。

# labelname list (name)

引用中打印的姓名。该列表可以是shortauthor, author, shorteditor, editor,或translator域的复制值,正常情况以该顺序检测。如果没有作者 (authors)和编者 (authors),该列表时未定义的。注意该列表也与use<name>相关,见§ 3.1.3。引用样式打印引用中的姓名时使用这一列表。提供该列表仅为方便起见,没有附加的意义。使用 Biber 时,该域可以定制,详见§ 4.5.9。

Biber only

#### labelnumber field (literal)

参考文献条目的序号,用于顺序编码类的样式。如果定义了shorthand域,Biblatex 不再给各条目赋予一个数值。这种情况下,labelnumber就是 shorthand 而不是一个数字。顺序编码类的样式必须使用该域的值而不是一个计数器值。注意:该域需要打开包选项labelnumber,详见§3.1.2.3。也可以参考§3.1.2.1节的defernumbers选项。

## prefixnumber field (literal)

If the prefixnumbers option of \printbibliography has been set in order to prefix all entries in a subbibliography with a fixed string, this string is available in the prefixnumber field of all affected entries. If no prefix has been set, the prefixnumber field of the respective entry is undefined. See the prefixnumbers option of \printbibliography in § 3.6.2 for details. If the shorthand field is defined, Biblatex does not assign the prefix to the prefixnumber field of the respective entry. In this case, the prefixnumber field is undefined.

#### labeltitle field (literal)

The printable title of a work. In some circumstances, a style might need to choose a title from a list of a possible title fields. For example, citation styles printing short titles may want to print the shorttitle field if it exists but otherwise print the title field. The list of fields to be considered when constructing labeltitle may be customized. See § 4.5.9 for details. Note that the extratitle field needs to be requested with the package option labeltitle, see § 3.1.2.3 for details. See also extratitle. Note also that the extratitleyear field needs to be requested with the package option labeltitleyear. See also extratitleyear.

## extratitle field (integer)

It is sometimes useful, for example in author-title citation schemes, to be able to disambiguate works with the same title. For works by the same labelname with the same labeltitle, the extratitle field holds an integer which may be converted to a letter with \mknumalph or formatted in some other way (or it can be merely used as a flag to say that some other field such as a date should be used in conjunction with the labeltitle field). This field is undefined if there is only one work with the same labeltitle by the same labelname in the bibliography. Note that the extratitle field needs to be requested with the package option labeltitle, see § 3.1.2.3 for details. See also labeltitle. Table 5 summarises the various extra\* disambiguation counters and what they track.

#### extratitleyear field (integer)

It is sometimes useful, for example in author-title citation schemes, to be able to disambiguate works with the same title in the same year but with no author. For works with the same labeltitle and with the same labelyear, the extratitleyear field

Biber only

holds an integer which may be converted to a letter with \mknumalph or formatted in some other way (or it can be merely used as a flag to say that some other field such as a publisher should be used in conjunction with the labelyear field). This field is undefined if there is only one work with the same labeltitle and labelyear in the bibliography. Note that the extratitleyear field needs to be requested with the package option labeltitleyear, see § 3.1.2.3 for details. See also labeltitleyear. Table 5 summarises the various extra\* disambiguation counters and what they track.

#### labelyear field (literal)

The publication year, as specified in the date or the year field, for use in author-year labels. A complete author-year label consists of the fields labelyear plus extrayear. Note that the labelyear and extrayear fields need to be requested with the package option labeldate, see § 3.1.2.3 for details. See also extrayear. With Biber, the source date field for this may be customized. See § 4.5.9 for details.

#### labelmonth field (datepart)

The publication month, as specified in the date or the month field, for use in authoryear labels. Note that the labelmonth field needs to be requested with the package option labeldate, see § 3.1.2.3 for details. With Biber, the source date field for this may be customized. See § 4.5.9 for details.

# Biber only

Biber only

## labelday field (datepart)

The publication day, as specified in the date, for use in author-year labels. Note that the labelday field needs to be requested with the package option labeldate, see § 3.1.2.3 for details. With Biber, the source date field for this may be customized. See § 4.5.9 for details.

# Biber only

# extrayear field (integer)

The author-year citation scheme usually requires a letter to be appended to the year if the bibliography contains two or more works by the same author which were all published in the same year. In this case, the extrayear field holds an integer which may be converted to a letter with \mknumalph or formatted in some other way. This field is undefined if there is only one work by the author in the bibliography or if all works by the author have different publication years. A complete author-year label consists of the fields labelyear plus extrayear. Note that the labelyear and extrayear fields need to be requested with the package option labeldate, see § 3.1.2.3 for details. See also labelyear. Table 5 summarises the various extra\* disambiguation counters and what they track.

**4.2.4.3 date 的组成域** See table 8 for an overview of how the date fields in bib files are related to the date fields provided by the style interface. When testing for a field like originate in a style, use code like:

bib File		Data Interface	Data Interface	
Field	Value (Example)	Field	Value (Example)	
date	1988	day	undefined	
		month	undefined	
		year	1988	
		endday	undefined	
		endmonth	undefined	
		endyear	undefined	
date	1997/	day	undefined	
		month	undefined	
		year	1997	
		endday	undefined	
		endmonth	undefined	
		endyear	empty	
urldate	2009-01-31	urlday	31	
		urlmonth	01	
		urlyear	2009	
		urlendday	undefined	
		urlendmonth	undefined	
		urlendyear	undefined	
origdate	2002-01/2002-02	origday	undefined	
		origmonth	01	
		origyear	2002	
		origendday	undefined	
		origendmonth	02	
		origendyear	2002	
eventdate	1995-01-31/1995-02-05	eventday	31	
		eventmonth	01	
		eventyear	1995	
		eventendday	05	
		eventendmonth	02	
		eventendyear	1995	

**Table 8: Date Interface** 

```
\iffieldundef{origyear}{...}{...}
```

This will tell you if the corresponding date is defined at all. This test:

```
\iffieldundef{origendyear}{...}{...}
```

will tell you if the corresponding date is defined and a (fully specified) range. This test:

```
\iffieldequalstr{origendyear}{}{...}{...}
```

will tell you if the corresponding date is defined and an open-ended range. Open-ended ranges are indicated by an empty endyear component (as opposed to an undefined endyear component). See § 2.3.8 and table 3 on page 46 for further examples.

# day field (datepart)

This field holds the day component of the date field. If the date is a range, it holds the day component of the start date.

#### month field (datepart)

This field is the month as given in the database file or it holds the month component of the date field. If the date is a range, it holds the month component of the start date.

#### year field (datepart)

This field is the year as given in the database file or it holds the year component of the date field. If the date is a range, it holds the year component of the start date.

#### endday field (datepart)

If the date specification in the date field is a range, this field holds the day component of the end date.

### endmonth field (datepart)

If the date specification in the date field is a range, this field holds the month component of the end date.

## endyear field (datepart)

If the date specification in the date field is a range, this field holds the year component of the end date. A blank (but defined) endyear component indicates an open ended date range.

#### origday field (datepart)

This field holds the day component of the originate field. If the date is a range, it holds the day component of the start date.

#### origmonth field (datepart)

This field holds the month component of the originate field. If the date is a range, it holds the month component of the start date.

# origyear field (datepart)

This field holds the year component of the originate field. If the date is a range, it holds the year component of the start date.

#### origendday field (datepart)

If the date specification in the originate field is a range, this field holds the day component of the end date.

## origendmonth field (datepart)

If the date specification in the originate field is a range, this field holds the month component of the end date.

#### origendyear field (datepart)

If the date specification in the origdate field is a range, this field holds the year component of the end date. A blank (but defined) origendyear component indicates an open ended origdate range.

### eventday field (datepart)

This field holds the day component of the eventdate field. If the date is a range, it holds the day component of the start date.

#### eventmonth field (datepart)

This field holds the month component of the eventdate field. If the date is a range, it holds the month component of the start date.

# eventyear field (datepart)

This field holds the year component of the eventdate field. If the date is a range, it holds the year component of the start date.

#### eventendday field (datepart)

If the date specification in the eventdate field is a range, this field holds the day component of the end date.

#### eventendmonth field (datepart)

If the date specification in the eventdate field is a range, this field holds the month component of the end date.

# eventendyear field (datepart)

If the date specification in the eventdate field is a range, this field holds the year component of the end date. A blank (but defined) eventendyear component indicates an open ended eventdate range.

#### urlday field (datepart)

This field holds the day component of the urldate field.

#### urlmonth field (datepart)

This field holds the month component of the urldate field.

#### urlyear field (datepart)

This field holds the year component of the urldate field.

#### urlendday field (datepart)

If the date specification in the urldate field is a range, this field holds the day component of the end date.

#### urlendmonth field (datepart)

If the date specification in the urldate field is a range, this field holds the month component of the end date.

#### urlendyear field (datepart)

If the date specification in the urldate field is a range, this field holds the year component of the end date. A blank (but defined) urlendyear component indicates an open ended urldate range.

# 4.3 标注样式 Citation Styles

标注样式是诸如\cite等用于打印不同类型标注的命令集。这些样式定义在后缀为cbx的文件中。Biblatex 在包末尾加载它们。注意:一些标准标注样式所共享的常用的宏集在biblatex.def文件中。这一文件也再包末尾加载,先于选择的标注样式。它也包含来自§3.7.5节的命令的定义。

# 4.3.1 标注样式文件 Citation Style Files

在讨论标注样式文件提供的各个命令前,考虑如下一个典型的cbx文件的整体结构:

```
\ProvidesFile{example.cbx}[2006/03/15 v1.0 biblatex citation style]
\DeclareCiteCommand{\cite}{...}{...}{...}
\DeclareCiteCommand{\parencite}[\mkbibparens]{...}{...}{...}
\DeclareCiteCommand{\footcite}[\mkbibfootnote]{...}{...}{...}
\DeclareCiteCommand{\textcite}{...}{...}{...}{...}
```

# $\RequireCitationStyle{\langle style \rangle}$

这个命令是可选的,用于在一些更一般的样式基础上构建特殊的标注样式。它加载标注样式style.cbx。

## $\InitializeCitationStyle\{\langle code\rangle\}\$

指定初始化或重设标注样式需要的任意〈code〉。这个钩子将在包加载的时候执行一次,并且每次都使用§3.7.8节的\citereset命令。\citereset命令也重设本宏包的内部标注追踪器。它会影响§4.6.2节中列出的cmdifciteseen,\ifentryseen,\ifciteibid,和\ifciteidem等判断。当使用refsection环境时,标注追踪器重设当前的refsection局部环境。

 $\OnManualCitation{\langle code \rangle}$ 指定标注样式部分重设需要的任意 $\langle code \rangle$ 。这一钩子将在§ 3.7.8中

的\mancite命令使用时调用。它有时特别有用,可以代替像'ibidem'或'op. cit.'等缩写表示的重复标注,因为当自动生成和人工产生的标注混合使用的时候这些缩写可能会有歧义。\mancite命令也会重设宏包的内部'ibidem'和'idem'追踪器,进而影响§4.6.2讨论的\ifciteibid和\ifciteidem判断。

This is the core command used to define all citation commands. It takes one optional and five mandatory arguments. The  $\langle command \rangle$  is the command to be defined, for example \cite. If the optional  $\langle wrapper \rangle$  argument is given, the entire citation will be passed to the \( \lambda mapper \rangle \) as an argument, i. e., the wrapper command must take one mandatory argument.<sup>29</sup> The \(\rangle precode \rangle\) is arbitrary code to be executed at the beginning of the citation. It will typically handle the *(prenote)* argument which is available in the prenote field. It may also be used to initialize macros required by the  $\langle loop code \rangle$ . The  $\langle loopcode \rangle$  is arbitrary code to be executed for each entry key passed to the  $\langle command \rangle$ . This is the core code which prints the citation labels or any other data. The \( \sep \code \) is arbitrary code to be executed after each iteration of the  $\langle loopcode \rangle$ . It will only be executed if a list of entry keys is passed to the (command). The (sepcode) will usually insert some kind of separator, such as a comma or a semicolon. The \(\langle postcode \rangle\) is arbitrary code to be executed at the end of the citation. The \(\rho postcode\)\ will typically handle the (postnote) argument which is available in the postnote field.<sup>30</sup> The starred variant of \DeclareCiteCommand defines a starred \( \chiommand \). For example, \DeclareCiteCommand\* {cite} would define \cite\*.31

 $\label{lem:decommand} $$ \ | \ \langle command \rangle | \ | \ \langle cite \rangle | \ \langle \langle cite \rangle | \$ 

This command defines 'multicite' commands (§ 3.7.3). The  $\langle command \rangle$  is the multicite command to be defined, for example  $\langle cites \rangle$ . It is automatically made robust. Multicite commands are built on top of backend commands defined with  $\langle cite \rangle$  argument specifies the name of the backend command to be used. Note that the wrapper of the backend command (i. e., the  $\langle wrapper \rangle$  argument passed to  $\langle cite \rangle$  argument of the backend command (i. e., the string to be printed as a separator between the individual citations in the list. This will typically be  $\langle cite \rangle$  is the following examples are real definitions taken from biblatex.def:

 $<sup>^{29}</sup> Typical \ examples \ of \ wrapper \ commands \ are \ \verb|\mkbibparens| and \ \verb|\mkbibfootnote|.$ 

<sup>&</sup>lt;sup>30</sup>The bibliographic data available to the  $\langle loopcode \rangle$  is the data of the entry currently being processed. In addition to that, the data of the first entry is available to the  $\langle precode \rangle$  and the data of the last one is available to the  $\langle postcode \rangle$ . 'First' and 'last' refer to the order in which the citations are printed. If the sortcites package option is active, this is the order of the list after sorting. Note that no bibliographic data is available to the  $\langle sepcode \rangle$ .

<sup>&</sup>lt;sup>31</sup>Note that the regular variant of \DeclareCiteCommand defines a starred version of the \( \chicommand \) implicitly, unless the starred version has been defined before. This is intended as a fallback. The implicit definition is an alias for the regular variant.

```
\DeclareAutoCiteCommand{\( \( name \) \) [\( position \) ] {\( cite \) \} {\( multicite \) \)}
```

This command provides definitions for the \autocite and \autocites commands from § 3.7.4. The definitions are enabled with the autocite package option from § 3.1.2.1. The  $\langle name \rangle$  is an identifier which serves as the value passed to the package option. The autocite commands are built on top of backend commands like \parencite and \parencites. The arguments  $\langle cite \rangle$  and  $\langle multicite \rangle$  specify the backend commands to use. The  $\langle cite \rangle$  argument refers to \autocite and  $\langle multicite \rangle$  refers to \autocites. The  $\langle position \rangle$  argument controls the handling of any punctuation marks after the citation. Possible values are 1, r, f. r means that the punctuation is placed to the right of the citation, i.e., it will not be moved around. 1 means that any punctuation after the citation is moved to the left of the citation. f is like r in a footnote and like 1 otherwise. This argument is optional and defaults to r. See also \DeclareAutoPunctuation in § 4.7.5 and the autopunct package option in § 3.1.2.1. The following examples are real definitions taken from biblatex.def:

```
\DeclareAutoCiteCommand{plain} {\cite} {\cites}
\DeclareAutoCiteCommand{inline} {\parencites} {\parencites}
\DeclareAutoCiteCommand{footnote} [1] {\footcite} {\footcites}
\DeclareAutoCiteCommand{footnote} [f] {\smartcite} {\smartcites}
```

A definition provided in the document preamble can be subsequently adopted with the following: (see § 3.2.2).

```
\ExecuteBibliographyOptions{autocite=name}
```

## 4.3.2 特殊域 Special Fields

The following fields are used by Biblatex to pass data to citation commands. They are not used in bib files but defined automatically by the package. From the perspective of a citation style, they are not different from the fields in a bib file. See also § 4.2.4.

```
prenote field (literal)
```

The  $\langle prenote \rangle$  argument passed to a citation command. This field is specific to citations and not available in the bibliography. If the  $\langle prenote \rangle$  argument is missing or empty, this field is undefined.

164

#### postnote field (literal)

The  $\langle postnote \rangle$  argument passed to a citation command. This field is specific to citations and not available in the bibliography. If the  $\langle postnote \rangle$  argument is missing or empty, this field is undefined.

#### multiprenote field (literal)

The  $\langle multiprenote \rangle$  argument passed to a multicite command. This field is specific to citations and not available in the bibliography. If the  $\langle multiprenote \rangle$  argument is missing or empty, this field is undefined.

# multipostnote field (literal)

The  $\langle \textit{multipostnote} \rangle$  argument passed to a multicite command. This field is specific to citations and not available in the bibliography. If the  $\langle \textit{multipostnote} \rangle$  argument is missing or empty, this field is undefined.

#### postpunct field (punctuation command)

The trailing punctuation argument implicitly passed to a citation command. This field is specific to citations and not available in the bibliography. If the character following a given citation command is not specified in \DeclareAutoPunctuation (§ 4.7.5), this field is undefined.

# 4.4 数据接口 Data Interface

The data interface are the facilities used to format and print all bibliographic data. These facilities are available in both bibliography and citation styles.

## 4.4.1 数据命令 Data Commands

This section introduces the main data interface of the Biblatex package. These are the commands doing most of the work, i. e., they actually print the data provided in lists and fields.

# \printfield[\langle format \rangle] { \langle field \rangle }

This command prints a  $\langle field \rangle$  using the formatting directive  $\langle format \rangle$ , as defined with \DeclareFieldFormat. If a type-specific  $\langle format \rangle$  has been declared, the type-specific formatting directive takes precedence over the generic one. If the  $\langle field \rangle$  is undefined, nothing is printed. If the  $\langle format \rangle$  is omitted, \printfield tries using the name of the field as a format name. For example, if the title field is to be printed and the  $\langle format \rangle$  is not specified, it will try to use the field format title. In this case, any type-specific formatting directive will also take precedence over the generic one. If all of these formats are undefined, it falls back to default as a last resort. Note that \printfield provides the name of the field currently being processed in \currentfield for use in field formatting directives.

 $<sup>^{32}</sup>In \ other \ words, \ printfield \{ \ title \} \ is \ equivalent \ to \ printfield [ \ title ] \}.$ 

```
\printlist[\langle format \rangle][\langle start \rangle - \langle stop \rangle] \{\langle literal \ list \rangle\}
```

This command loops over all items in a  $\langle literal \ list \rangle$ , starting at item number  $\langle start \rangle$  and stopping at item number  $\langle stop \rangle$ , including  $\langle start \rangle$  and  $\langle stop \rangle$  (all lists are numbered starting at 1). Each item is printed using the formatting directive  $\langle format \rangle$ , as defined with \DeclareListFormat. If a type-specific  $\langle format \rangle$  has been declared, the type-specific formatting directive takes precedence over the generic one. If the  $\langle literal \ list \rangle$  is undefined, nothing is printed. If the  $\langle format \rangle$  is omitted, \printlist tries using the name of the list as a format name. In this case, any type-specific formatting directive will also take precedence over the generic one. If all of these formats are undefined, it falls back to default as a last resort. The  $\langle start \rangle$  argument defaults to 1;  $\langle stop \rangle$  defaults to the total number of items in the list. If the total number is greater than  $\langle maxitems \rangle$ ,  $\langle stop \rangle$  defaults to  $\langle minitems \rangle$  (see § 3.1.2.1). See \printnames for further details. Note that \printlist provides the name of the literal list currently being processed in \currentlist for use in list formatting directives.

```
\printnames [\langle format \rangle] [\langle start \rangle - \langle stop \rangle] {\langle name \ list \rangle}
```

This command loops over all items in a  $\langle name \ list \rangle$ , starting at item number  $\langle start \rangle$  and stopping at item number  $\langle stop \rangle$ , including  $\langle start \rangle$  and  $\langle stop \rangle$  (all lists are numbered starting at 1). Each item is printed using the formatting directive  $\langle format \rangle$ , as defined with \DeclareNameFormat. If a type-specific  $\langle format \rangle$  has been declared, the type-specific formatting directive takes precedence over the generic one. If the  $\langle name \ list \rangle$  is undefined, nothing is printed. If the  $\langle format \rangle$  is omitted, \DeclareNames tries using the name of the list as a format name. In this case, any type-specific formatting directive will also take precedence over the generic one. If all of these formats are undefined, it falls back to default as a last resort. The  $\langle start \rangle$  argument defaults to 1;  $\langle stop \rangle$  defaults to the total number of items in the list. If the total number is greater than  $\langle maxnames \rangle$ ,  $\langle stop \rangle$  defaults to  $\langle minnames \rangle$  (see § 3.1.2.1). If you want to select a range but use the default list format, the first optional argument must still be given, but is left empty:

```
\printnames[][1-3]{...}
```

One of  $\langle start \rangle$  and  $\langle stop \rangle$  may be omitted, hence the following arguments are all valid:

```
\printnames[...][-1]{...}
\printnames[...][2-]{...}
\printnames[...][1-3]{...}
```

If you want to override  $\langle maxnames \rangle$  and  $\langle minnames \rangle$  and force printing of the entire list, you may refer to the listtotal counter in the second optional argument:

```
\printnames[...][-\value{listtotal}]{...}
```

Whenever \printnames and \printlist process a list, information concerning the current state is accessible by way of four counters: the listtotal counter holds the total number of items in the current list, listcount holds the number of the item currently being processed, liststart is the \( \start \) argument passed to \printnames or \printlist, liststop is the \langle stop \rangle argument. These counters are intended for use in list formatting directives. listtotal may also be used in the second optional argument to \printnames and \printlist. Note that these counters are local to list formatting directives and do not hold meaningful values when used anywhere else. For every list, there is also a counter by the same name which holds the total number of items in the corresponding list. For example, the author counter holds the total number of items in the author list. These counters are similar to listtotal except that they may also be used independently of list formatting directives. There are also maxnames and minnames as well as maxitems and minitems counters which hold the values of the corresponding package options. See § 4.10.5 for a complete list of such internal counters. Note that \printnames provides the name of the name list currently being processed in \currentname for use in name formatting directives.

\printtext [\langle format \rangle] {\langle text \rangle} 该命令用于打印\langle text \rangle, 可以是可打印的文本或者任意产生可打印文本的代码。它清除插入\langle text \rangle 之前的标点缓存并且通知 Biblatex 打印文本已经插入。这保证了所有之前和之后的\newblock和\newunit命令能产生期望的作用。\printfield、\printnames、\bibstring及其相关命令都这般自动处理(见 § 4.8)。如果一个参考文献样式需要如实插入文本(包括来自 §§ 4.7.3 and 4.7.4的命令),需要使用该命令来确保 block 和 unit 标点在 § 4.7.1节中所述正常功能。可选参数\format\指定一个域格式指令用于格式化\langle text \rangle 。当需要把若干个域打印为某一格式的集合块,这就会很有用,比如把集合块用括号或引号包起来。如果声明了 type-specific 的格式指令,则覆盖设置的一般格式指令。如果\format\缺省,那么\text\如实输出(原样打印)。更多实用细节见第 § 4.11.7节。

#### \printfile[\langle format \rangle] \{ \langle file \rangle \}

This command is similar to \printtext except that the second argument is a file name rather than literal text. The  $\langle file \rangle$  argument must be the name of a valid LaTeX file found in TeX's search path. \printfile will use \input to load this  $\langle file \rangle$ . If there is no such file, \printfile does nothing. The optional  $\langle format \rangle$  argument specifies a field formatting directive to be applied to the  $\langle file \rangle$ . If a type-specific  $\langle format \rangle$  has been declared, the type-specific formatting directive takes precedence over the generic one. If the  $\langle format \rangle$  is omitted, the  $\langle file \rangle$  is printed as is. Note that this feature needs to be enabled explicitly by setting the package option loadfiles from § 3.1.2.1. By default, \printfile will not input any files.

\printdate This command prints the date of the entry, as specified in the fields date or month/
year. The date format is controlled by the package option date from § 3.1.2.1. Additional formatting (fonts etc.) may be applied by adjusting the field format date

(§ 4.10.4). Note that this command interfaces with the punctuation tracker. There is no need to wrap it in a \printtext command.

\printdateextra Similar to \printdate but incorporates the extrayear field in the date specification. This is useful for bibliography styles designed for author-year citations.

\printdatelabel Similar to \printdate but prints the date field determined by \DeclareLabeldate. The date format is controlled by the package option datelabel from § 3.1.2.1. Additional formatting may be applied by adjusting the field format datelabel (§ 4.10.4).

\printdateextralabel Similar to \printdatelabel but incorporates the extrayear field in the date specification. This is useful for bibliography styles designed for author-year citations.

\printurldate Similar to \printdate but prints the urldate of the entry. The date format is controlled by the package option urldate from § 3.1.2.1. Additional formatting may be applied by adjusting the field format urldate (§ 4.10.4).

\printorigdate Similar to \printdate but prints the origdate of the entry. The date format is controlled by the package option origdate from § 3.1.2.1. Additional formatting may be applied by adjusting the field format origdate (§ 4.10.4).

\printeventdate Similar to \printdate but prints the eventdate of the entry. The date format is controlled by the package option eventdate from § 3.1.2.1. Additional formatting may be applied by adjusting the field format eventdate (§ 4.10.4).

 $\indexfield[\langle format \rangle] \{\langle field \rangle\}$ 

This command is similar to \printfield except that the  $\langle field \rangle$  is not printed but added to the index using the formatting directive  $\langle format \rangle$ , as defined with \peclareIndexFieldFormat. If a type-specific  $\langle format \rangle$  has been declared, it takes precedence over the generic one. If the  $\langle field \rangle$  is undefined, this command does nothing. If the  $\langle format \rangle$  is omitted, \indexfield tries using the name of the field as a format name. In this case, any type-specific formatting directive will also take precedence over the generic one. If all of these formats are undefined, it falls back to default as a last resort.

 $\indexlist[\langle format \rangle][\langle start \rangle - \langle stop \rangle] \{\langle literal \ list \rangle\}$ 

This command is similar to \printlist except that the items in the list are not printed but added to the index using the formatting directive  $\langle format \rangle$ , as defined with \DeclareIndexListFormat. If a type-specific  $\langle format \rangle$  has been declared, the type-specific formatting directive takes precedence over the generic one. If the  $\langle literal\ list \rangle$  is undefined, this command does nothing. If the  $\langle format \rangle$  is omitted, \indexlist tries using the name of the list as a format name. In this case, any type-specific formatting directive will also take precedence over the generic one. If all of these formats are undefined, it falls back to default as a last resort.

```
\indexnames [\langle format \rangle] [\langle start \rangle - \langle stop \rangle] \{\langle name \ list \rangle\}
```

This command is similar to \printnames except that the items in the list are not printed but added to the index using the formatting directive  $\langle format \rangle$ , as defined with \DeclareIndexNameFormat. If a type-specific  $\langle format \rangle$  has been declared, the type-specific formatting directive takes precedence over the generic one. If the  $\langle name\ list \rangle$  is undefined, this command does nothing. If the  $\langle format \rangle$  is omitted, \indexnames tries using the name of the list as a format name. In this case, any type-specific formatting directive will also take precedence over the generic one. If all of these formats are undefined, it falls back to default as a last resort.

```
\entrydata\{\langle key \rangle\} \{\langle code \rangle\}
\entrydata*\{\langle key \rangle\} \{\langle code \rangle\}
```

Data commands like \printfield normally use the data of the entry currently being processed. You may use \entrydata to switch contexts locally. The  $\langle key \rangle$  is the entry key of the entry to use locally. The  $\langle code \rangle$  is arbitrary code to be executed in this context. This code will be executed in a group. See § 4.11.6 for an example. Note that this command will automatically switch languages if the autolang package option is enabled. The starred version \entrydata\* will clone all fields of the enclosing entry, using field, counter, and other resource names prefixed with the string 'saved'. This is useful when comparing two data sets. For example, inside the  $\langle code \rangle$  argument, the author field holds the author of entry  $\langle key \rangle$  and the author of the enclosing entry is available as savedauthor. The author counter holds the number of names in the author field of  $\langle key \rangle$ ; the savedauthor counter refers to the author count of the enclosing entry.

```
\entryset{\(\rho recode\)\)} {\(\rho stcode\)\}
```

This command is intended for use in bibliography drivers handling @set entries. It will loop over all members of the set, as indicated by the entryset field, and execute the appropriate driver for the respective set member. This is similar to executing the \usedriver command from § 4.6.4 for each set member. The  $\langle precode \rangle$  is arbitrary code to be executed prior to processing each item in the set. The  $\langle postcode \rangle$  is arbitrary code to be executed immediately after processing each item. Both arguments are mandatory in terms of the syntax but may be left empty. See § 4.11.1 for usage examples.

```
\DeclareFieldInputHandler{\langle field \rangle} {\langle code \rangle}
```

This command can be used to define a data input handler for  $\langle field \rangle$  when it is read from the .bbl. Within the  $\langle code \rangle$ , the macro \NewValue contains the value of the field. For example, to ignore the volumes field when it appears, you could do

```
\DeclareFieldInputHandler{volumes} {\def\NewValue{}}
```

Generally, you would want to use \DeclareSourcemap (see § 4.5.2) to remove and modify fields but this alternative method may be useful in some circumstances when the emphasis is on appearance rather than data since the  $\langle code \rangle$  can be arbitraty TeX.

```
\DeclareListInputHandler\{\langle \mathit{list}\rangle\}\{\langle \mathit{code}\rangle\}
```

As  $\DeclareFieldInputHandler$  but for lists. Within the  $\langle code \rangle$ , the macro  $\NewValue$  contains the value of the list and  $\NewCount$  contains the number of items in the list.

```
\DeclareNameInputHandler\{\langle name \rangle\} \{\langle code \rangle\}
```

As  $\DeclareFieldInputHandler$  but for names. Within the  $\langle code \rangle$ , the macro  $\NewValue$  contains the value of the name,  $\NewCount$  contains the number of individual names in the name and  $\NewOption$  contains any per-name options passed in the .bbl.

## 4.4.2 格式化指令 Formatting Directives

This section introduces the commands used to define the formatting directives required by the data commands from § 4.4.1. Note that all standard formats are defined in biblatex.def.

Defines the field format  $\langle format \rangle$ . This formatting directive is arbitrary  $\langle code \rangle$  to be executed by \printfield. The value of the field will be passed to the  $\langle code \rangle$  as its first and only argument. The name of the field currently being processed is available to the  $\langle code \rangle$  as \currentfield. If an  $\langle entrytype \rangle$  is specified, the format is specific to that type. The  $\langle entrytype \rangle$  argument may be a comma-separated list of values. The starred variant of this command is similar to the regular version, except that all type-specific formats are cleared.

Defines the literal list format  $\langle format \rangle$ . This formatting directive is arbitrary  $\langle code \rangle$  to be executed for every item in a list processed by \printlist. The current item will be passed to the  $\langle code \rangle$  as its first and only argument. The name of the literal list currently being processed is available to the  $\langle code \rangle$  as \currentlist. If an  $\langle entrytype \rangle$  is specified, the format is specific to that type. The  $\langle entrytype \rangle$  argument may be a commaseparated list of values. Note that the formatting directive also handles the punctuation to be inserted between the individual items in the list. You need to check whether you are in the middle of or at the end of the list, i.e., whether listcount is smaller than or equal to liststop. The starred variant of this command is similar to the regular version, except that all type-specific formats are cleared.

```
\DeclareNameFormat [\langle entrytype, ... \rangle] {\langle format \rangle} {\langle code \rangle} \DeclareNameFormat* {\langle format \rangle} {\langle code \rangle}
```

Defines the name list format  $\langle format \rangle$ . This formatting directive is arbitrary  $\langle code \rangle$  to be executed for every name in a list processed by \printnames. If an  $\langle entrytype \rangle$  is specified, the format is specific to that type. The  $\langle entrytype \rangle$  argument may be a comma-separated list of values. The individual parts of a name will be passed to the  $\langle code \rangle$  as separate arguments. These arguments are as follows:

- #1 The last names. If a name consists of a single part only (for example, 'Aristotle'), this part will be treated as the last name.
- #2 The last names, given as initials.
- #3 The first names. This argument also includes all middle names.
- #4 The first names, given as initials.
- #5 The name prefixes, for example von, van, of, da, de, del, della, etc. Note that name prefixes are referred to as the 'von part' of the name in the BibTeX file format documentation.
- #6 The name prefixes, given as initials.
- #7 The name affixes, for example 'junior', 'senior', 'der Jüngere', 'der Ältere', etc. Note that name affixes are referred to as the 'junior part' of the name in the BibTeX file format documentation.
- #8 The name affixes, given as initials.

If a certain part of a name is not available, the corresponding argument will be empty, hence you may use \ifblank tests to check for the individual parts of a name. The name of the name list currently being processed is available to the  $\langle code \rangle$  as \currentname. Note that the formatting directive also handles the punctuation to be inserted between separate names and between the individual parts of a name. You need to check whether you are in the middle of or at the end of the list, i. e., whether listcount is smaller than or equal to liststop. See also § 3.12.4. The starred variant of this command is similar to the regular version, except that all type-specific formats are cleared.

```
\DeclareIndexFieldFormat [\langle entrytype, ... \rangle] {\langle format \rangle} {\langle code \rangle} \DeclareIndexFieldFormat*{\langle format \rangle} {\langle code \rangle}
```

Defines the field format  $\langle format \rangle$ . This formatting directive is arbitrary  $\langle code \rangle$  to be executed by \indexfield. The value of the field will be passed to the  $\langle code \rangle$  as its first and only argument. The name of the field currently being processed is available to the  $\langle code \rangle$  as \currentfield. If an  $\langle entrytype \rangle$  is specified, the format is specific to that type. The  $\langle entrytype \rangle$  argument may be a comma-separated list of values. This command is similar to \DeclareFieldFormat except that the data handled by the  $\langle code \rangle$  is not intended to be printed but written to the index. Note that \indexfield

will execute the  $\langle code \rangle$  as is, i. e., the  $\langle code \rangle$  must include \index or a similar command. The starred variant of this command is similar to the regular version, except that all type-specific formats are cleared.

Defines the literal list format  $\langle format \rangle$ . This formatting directive is arbitrary  $\langle code \rangle$  to be executed for every item in a list processed by \indexlist. The current item will be passed to the  $\langle code \rangle$  as its only argument. The name of the literal list currently being processed is available to the  $\langle code \rangle$  as \currentlist. If an  $\langle entrytype \rangle$  is specified, the format is specific to that type. The  $\langle entrytype \rangle$  argument may be a comma-separated list of values. This command is similar to \DeclareListFormat except that the data handled by the  $\langle code \rangle$  is not intended to be printed but written to the index. Note that \indexlist will execute the  $\langle code \rangle$  as is, i. e., the  $\langle code \rangle$  must include \index or a similar command. The starred variant of this command is similar to the regular version, except that all type-specific formats are cleared.

```
\label{localize} $$ \DeclareIndexNameFormat [$\langle entrytype, ... \rangle] {$\langle format \rangle$} {\langle code \rangle$} $$ \DeclareIndexNameFormat*{$\langle format \rangle$} {\langle code \rangle$} $$
```

Defines the name list format  $\langle format \rangle$ . This formatting directive is arbitrary  $\langle code \rangle$  to be executed for every name in a list processed by  $\indexnames$ . The name of the name list currently being processed is available to the  $\langle code \rangle$  as  $\indexnames$ . If an  $\langle entrytype \rangle$  is specified, the format is specific to that type. The  $\langle entrytype \rangle$  argument may be a comma-separated list of values. The parts of the name will be passed to the  $\langle code \rangle$  as separate arguments. This command is very similar to  $\indexnames$  Note that  $\indexnames$  will execute the  $\langle code \rangle$  as is, i. e., the  $\langle code \rangle$  must include  $\index$  or a similar command. The starred variant of this command is similar to the regular version, except that all type-specific formats are cleared.

```
\DeclareFieldAlias[\langle entry\ type \rangle] \{\langle alias \rangle\} [\langle format\ entry\ type \rangle] \{\langle format \rangle\}
```

Declares  $\langle alias \rangle$  to be an alias for the field format  $\langle format \rangle$ . If an  $\langle entrytype \rangle$  is specified, the alias is specific to that type. The  $\langle format\ entry\ type \rangle$  is the entry type of the backend format. This is only required when declaring an alias for a type-specific formatting directive.

```
\DeclareListAlias[\langle entry type \rangle] \{ \langle alias \rangle \} [\langle format entry type \rangle] \{ \langle format \rangle type \rangle \}
```

Declares  $\langle alias \rangle$  to be an alias for the literal list format  $\langle format \rangle$ . If an  $\langle entrytype \rangle$  is specified, the alias is specific to that type. The  $\langle format\ entry\ type \rangle$  is the entry type of the backend format. This is only required when declaring an alias for a type-specific formatting directive.

```
\DeclareNameAlias[\langle entry\ type \rangle] \{\langle alias \rangle\} [\langle format\ entry\ type \rangle] \{\langle format \rangle\}
```

Declares  $\langle alias \rangle$  to be an alias for the name list format  $\langle format \rangle$ . If an  $\langle entrytype \rangle$  is specified, the alias is specific to that type. The  $\langle format\ entry\ type \rangle$  is the entry type of the backend format. This is only required when declaring an alias for a type-specific formatting directive.

```
\DeclareIndexFieldAlias[\langle entry\ type\rangle] \{\langle alias\rangle\}[\langle format\ entry\ type\rangle] \{\langle format\rangle\}
```

Declares  $\langle alias \rangle$  to be an alias for the field format  $\langle format \rangle$ . If an  $\langle entrytype \rangle$  is specified, the alias is specific to that type. The  $\langle format\ entry\ type \rangle$  is the entry type of the backend format. This is only required when declaring an alias for a type-specific formatting directive.

```
\DeclareIndexListAlias[\langle entry\ type\rangle] \{\langle alias\rangle\}[\langle format\ entry\ type\rangle] \{\langle format\rangle\}
```

Declares  $\langle alias \rangle$  to be an alias for the literal list format  $\langle format \rangle$ . If an  $\langle entrytype \rangle$  is specified, the alias is specific to that type. The  $\langle format\ entry\ type \rangle$  is the entry type of the backend format. This is only required when declaring an alias for a type-specific formatting directive.

```
\DeclareIndexNameAlias[\langle entry\ type \rangle] \{\langle alias \rangle\} [\langle format\ entry\ type \rangle] \{\langle format \rangle\}
```

Declares  $\langle alias \rangle$  to be an alias for the name list format  $\langle format \rangle$ . If an  $\langle entrytype \rangle$  is specified, the alias is specific to that type. The  $\langle format\ entry\ type \rangle$  is the entry type of the backend format. This is only required when declaring an alias for a type-specific formatting directive.

# 4.5 自定义 Customization

# 4.5.1 关联条目 Related Entries

关联条目功能由如下部分构成:33

- 可将条目中的特殊域用于建立和描述关系
- 可把本地化字符串作为关联数据的前缀 (可选)
- 提供用于抽取和打印关联数据的宏
- 提供给本地化字符串和关联数据格式化的格式

特殊域是related, relatedtype, relatedstring和 relatedoptions:

related 与当前文献某种程度关联的文献的关键词的分离列表<sup>34</sup>。注意: 关键词<sup>35</sup>的顺序很重要。来自多个关联文献的数据是按该域中关键词的顺序打印。

<sup>&</sup>lt;sup>33</sup>这里 related data 用关联而不是相关,其它地方用到相关的应一并改过来

<sup>34</sup>这里 separated list 用分离列表有没有更好的说法

<sup>35</sup>这里的 key 关键词应该是引用关键词,即 bibtex 键

relatedtype

The type of relationship. This serves three purposes. If the value of this field resolves to a localization string identifier, then the resulting localized string is printed before the data from the related entries. Secondly, if there is a macro called related:  $\langle relatedtype \rangle$ , this is used to format the data from the related entries. If no such macro exists, then the macro related: default is used. Lastly, if there is a format named related:  $\langle relatedtype \rangle$ , then it is used to format both the localized string and related entry data. If there is no related type specific format, the related format is used.

relatedstring

If an entry contains this field, then if value of the field resolves to a localization string identifier, the localization key value specified is printed before data from the related entries. If the field does not specify a localization key, its value is printed literally. If both relatedtype and relatedstring are present in an entry, relatedstring is used for the pre-data string (but relatedtype is still used to determine the macro and format to use when printing the data).

relatedoptions

A list of per-entry options to set on the related entry (actually on the clone of the related entry which is used as a data source—the actual related entry is not modified because it might be cited directly itself).

The related entry feature is enabled by default by the package option related from § 3.1.2.1. The related information entry data from the related entries is included via a \usebibmacro {related} call. Standard styles call this macro towards the end of each driver. Style authors should ensure the existence of (or take note of existing) localization strings which are useful as values for the relatedtype field, such as translation of or perhaps translated as. A plural variant can be identified with the localization key (relatedtype)s. This key's corresponding string is printed whenever more than one entry is specified in related. Bibliography macros and formatting directives for printing entries related by \( \textit{related type} \) should be defined using the name related: (relatedtype). The file biblatex.def contains macros and formats for some common relation types which can be used as templates. In particular, the \entrydata\* command is essential in such macros in order to make the data of the related entries available. Examples of entries using this feature can be found in the Biblatex distribution examples file biblatex-examples.bib. There are some specific formatting macros for this feature which control delimiters and separators in related entry information, see § 4.10.1.

#### 4.5.2 数据动态修改 Dynamic Modification of Data

Bibliographic data sources which are automatically generated or which you have no control over can be a problem if you need to edit them in some way. For this reason, Biber has the ability to modify data as it is read so that you can apply modifications to the source data stream without actually changing it. The modification can be defined in Biber's config file (see Biber docs), or via Biblatex macros in which case you can apply the modification only for specific documents, styles or globally.

Source mappings can be defined at different "levels" which are applied in a defined order. See the Biblatex manual regarding these macros:

```
user-level maps defined with \DeclareSourcemap \to user-level maps defined in the Biber config file (see Biber docs) \to style-level maps defined with \DeclareStyleSourcemap \to driver-level maps defined with \DeclareDriverSourcemap
```

```
\DeclareSourcemap { \langle specification \rangle }
```

Biber only

Defines source data modification (mapping) rules which can be used to perform any combination of the following tasks:

- •Map data source entrytypes to different entrytypes
- •Map datasource fields to different fields
- •Add new fields to an entry
- •Remove fields from an entry
- •Modify the contents of a field using standard Perl regular expression match and replace
- •Restrict any of the above operations to entries coming from particular datasources which you defined in \addresource macros
- •Restrict any of the above operations to entries only of a certain entrytype

The  $\langle specification \rangle$  is an undelimited list of \maps directives which specify containers for mappings rules applying to a particular data source type (§ 3.6.1). Spaces, tabs, and line endings may be used freely to visually arrange the  $\langle specification \rangle$ . Blank lines are not permissible. This command may only be used in the preamble and may only be used once—subsequent uses will overwrite earlier definitions.

```
\maps { \langle elements \rangle }
```

Contains an ordered set of \map elements each of which is a logically related set of mapping steps to apply to the data source.

```
datatype=bibtex, biblatexml, ris, zoterordfxml, default: bibtex endnotexml
```

Data source type to which the contained \map directives apply (§ 3.6.1).

```
overwrite=true, false default: false
```

Specify whether a mapping rule is allowed to overwrite already existing data in an entry. If this option is not specified, the default is false. The short form overwrite is equivalent to overwrite=true.

```
\mathbb{map} \{ \langle restrictions, steps \rangle \}
```

A container for an ordered set of map \steps, optionally restricted to particular entrytypes or data sources. This is a grouping element to allow a set of mapping steps to apply only to specific entrytypes or data sources. Mapping steps must always be contained within a \map element.

```
overwrite=true, false
```

As the same option on the parent \maps element. This option allows an override on a per-map group basis. If this option is not specified, the default is the parent \maps element option value. The short form overwrite is equivalent to overwrite = true.

```
\perdatasource { \langle datasource \rangle \}
```

Restricts all \steps in this \map element to entries from the named  $\langle datasource \rangle$ . The  $\langle datasource \rangle$  name should be exactly as given in a \addresource macro defining a data source for the document. Multiple \perdatasource restrictions are allowed within a \map element.

```
\pertype { \langle entrytype \rangle }
```

Restricts all \steps in this \map element to entries of the named \( \lambda entrytype \rangle \). Multiple \pertype restrictions are allowed within a \map element.

```
\pernottype { \langle entrytype \rangle }
```

Restricts all \steps in this \map element to entries not of the named \( \langle entrytype \rangle \). Multiple \pernottype restrictions are allowed within a \map element.

#### \step

A mapping step. Each step is applied sequentially to every relevant entry where 'relevant' means those entries which correspond to the data source type, entrytype and data source name restrictions mentioned above. Each step is applied to the entry as it appears after the application of all previous steps. The mapping performed by the step is determined by the following options:

```
typesource=\langle entrytype \rangle
typetarget=\langle entrytype \rangle
fieldsource=\langle entryfield \rangle
fieldtarget=\langle entryfield \rangle
match=\langle regexp \rangle
notmatch=\langle regexp \rangle
replace=\langle regexp \rangle
fieldset=\langle entryfield \rangle
```

```
fieldvalue=(string)
entryclone=\(\langle string \rangle \)
entrynull=true, false
                                                             default: false
                                                             default: false
append=true, false
final=true.false
                                                             default: false
null=true.false
                                                             default: false
                                                             default: false
origfield=true, false
                                                             default: false
origfieldval=true, false
origentrytype=true, false
                                                             default: false
```

For all boolean \step options, the short form option is equivalent to option = true. The following rules for a mapping step apply:

- •If entrynull is set, processing of the \map immediately terminates and the current entry is not created. It is as if it did not exist in the datasource. Obviously, you should select the entries which you want to apply this to using prior mapping steps.
- •If entryclone is set, a clone of the entry is created with an entry key prefixed by prefix. Obviously this may cause labelling problems in author/year styles etc. and should be used with care. It is mainly intended for numbering issues with numeric styles and multiple bibliographies where the same entries occur in more than one bibliography.
- •Change the typesource  $\langle entrytype \rangle$  to the typetarget  $\langle entrytype \rangle$ , if defined. If final is true then if the  $\langle entrytype \rangle$  of the entry is not typesource, processing of the parent \map immediately terminates.
- •Change the fieldsource  $\langle entry field \rangle$  to fieldtarget, if defined. If final is true then if there is no fieldsource  $\langle entry field \rangle$  in the entry, processing of the parent \map immediately terminates.
- •If match is defined but replace is not, only apply the step if the fieldsource  $\langle entry field \rangle$  matches the match regular expression (logic is reversed if you use notmatch instead)<sup>36</sup>. You may use capture parenthesis as usual and refer to these (\$1...\$9) in later fieldvalue specifications. This allows you to pull out parts of some fields and put these parts in other fields.
- •Perform a regular expression match and replace on the value of the fieldsource (entryfield) if match and replace are defined.
- •If fieldset is defined, then its value is  $\langle entry field \rangle$  which will be set to a value specified by further options. If overwrite is false for this step and the field to set already exists then the map step is ignored. If final is also true for this step,

<sup>36</sup>Regular expressions are full Perl 5.16 regular expressions. This means you may need to deal with special characters, see examples.

then processing of the parent map stops at this point. If append is true, then the value to set is appended to the current value of  $\langle entry field \rangle$ . The value to set is specified by a mandatory one and only one of the following options:

- o fieldvalue The fieldset  $\langle \mathit{entryfield} \rangle$  is set to the fieldvalue  $\langle \mathit{string} \rangle$
- $\circ$  null The fieldset  $\langle entry field \rangle$  is ignored, as if it did not exist in the datasource
- o origentrytype The fieldset  $\langle entryfield \rangle$  is set to the most recently mentioned typesource  $\langle entrytype \rangle$  name
- o origfield The fieldset  $\langle entry field \rangle$  is set to the most recently mentioned fieldsource  $\langle entry field \rangle$  name
- o originieldval The fieldset  $\langle \textit{entryfield} \rangle$  is set to the most recently mentioned fieldsource value

With BibTeX and RIS datasources, you may specify the pseudo-field entrykey for fieldsource which is the citation key of the entry. Naturally, this 'field' cannot be changed (used as fieldset, fieldtarget or changed using replace).

### \DeclareStyleSourcemap { \langle specification \rangle }

Biber only

This command sets the source mappings used by a style. Such mappings are conceptually separate from user mappings defined with \DeclareSourcemap and are applied directly after user maps. The syntax is identical to \DeclareSourcemap. This command is provided for style authors so that any maps defined for the style do not interfere with user maps or the default driver maps defined with \DeclareDriverSourcemap. This command is for use in style files and can only be used once—subsequent uses will overwrite earlier definitions.

#### $\DeclareDriverSourcemap[\langle datatype=driver \rangle] \{\langle specification \rangle\}$

Biber only

This command sets the driver default source mappings for the specified  $\langle driver \rangle$ . Such mappings are conceptually separate from user mappings defined with \DeclareSourcemap and style mapping defined with \DeclareStyleSourcemap. They consist of mappings which are part of the driver setup. Users should not normally need to change these. Driver default mapping are applied after user mappings (\DeclareSourcemap) and style mappings (\DeclareStyleSourcemap). These defaults are described in Appendix § A. The  $\langle specification \rangle$  is identical to that for \DeclareSourcemap but without the \maps elements: the  $\langle specification \rangle$  is just a list of \map elements since each \DeclareDriverSourcemap only applies to one datatype driver. See the default definitions in Appendix § A for examples.

Here are some data source mapping examples:

```
\DeclareSourcemap{
  \maps[datatype=bibtex] {
    \map{
      \perdatasource{example1.bib}
      \perdatasource{example2.bib}
      \step[fieldset=keywords, fieldvalue={keyw1, keyw2}]
      \step[fieldsource=entrykey]
      \step[fieldset=note, origfieldval]
    }
}
```

This would add a keywords field with value 'keyw1, keyw2' and set the note field to the entry key to all entries which are found in either the examples1.bib or examples2.bib files.

```
\DeclareSourcemap{
  \maps[datatype=bibtex] {
    \map{
     \step[fieldsource=title]
     \step[fieldset=note, origfieldval]
     }
}
```

Copy the title field to the note field unless the note field already exists.

```
\DeclareSourcemap{
  \maps[datatype=bibtex] {
    \map{
     \step[typesource=chat, typetarget=customa, final]
     \step[fieldset=type, origentrytype]
     }
}
```

Any chat entrytypes would become customa entrytypes and would automatically have a type field set to 'chat' unless the type field already exists in the entry (because overwrite is false by default). This mapping applies only to entries of type @chat since the first step has final set and so if the typesource does not match the entry entrytype, processing of this \map immediately terminates.

```
\DeclareSourcemap{
  \maps[datatype=bibtex] {
    \map{
```

179

```
\perdatasource{examples.bib}
  \pertype{article}
  \pertype{book}
  \step[fieldset=abstract, null]
  \step[fieldset=note, fieldvalue={Auto-created this field}]
}
}
}
```

Any entries of entrytype @article or @book from the examples.bib datasource would have their abstract fields removed and a note field added with value 'Autocreated this field'.

```
\DeclareSourcemap{
  \maps[datatype=bibtex] {
    \map{
      \step[fieldset=abstract, null]
      \step[fieldsource=conductor, fieldtarget=namea]
      \step[fieldsource=gps, fieldtarget=usera]
    }
}
```

This removes abstract fields from any entry, changes conductor fields to namea fields and changes gps fields to usera fields.

```
\DeclareSourcemap{
  \maps[datatype=bibtex]{
    \map{
      \step[fieldsource=pubmedid, fieldtarget=eprint, final]
      \step[fieldset=eprinttype, origfield]
      \step[fieldset=userd, fieldvalue={Some string of things}]
    }
}
```

Applies only to entries with pubmed fields and maps pubmedid fields to eprint fields, sets the eprinttype field to 'pubmedid' and also sets the userd field to the string 'Some string of things'.

180

```
replace=\regexp{\L$1}]
}
}
```

Here, the contents of the series field have leading numbers stripped and the remainder of the contents lowercased. Since regular expressions usually contain all sort of special characters, it is best to enclose them in the provided \regexp macro as shown—this will pass the expression through to Biber correctly.

Here, if for an entry, the maintitle field matches a particular regular expression, we set a special keyword so we can, for example, make a references section just for certain items.

```
\DeclareSourcemap{
  \maps[datatype=bibtex] {
    \map{
      \step[fieldsource=lista, match=\regexp{regexp}, final]
      \step[fieldset=lista, null]
    }
}
```

If an entry has a lista field which matches regular expression 'regexp', then it is removed.

```
\DeclareSourcemap{
  \maps[datatype=bibtex] {
    \map[overwrite=false] {
      \step[fieldsource=author]
      \step[fieldset=editor, origfieldval, final]
      \step[fieldsource=editor, match=\regexp{\A(.+?)\s+and.*}, replace={$1}
    }
}
```

For any entry with an author field, try to set sortname to the same as author. If this fails because sortname already exists, stop, otherwise truncate sortname to just the first name in the name list.

Here, we use multiple match/replace for the same field to regularise some inconstant name variants. Bear in mind that \step processing within a map element is sequential and so the changes from a previous \steps are already committed. Note that we don't need the \regexp macro to protect the regular expressions in this example as they contain no characters which need special escaping. Please note that due to the difficulty of protecting regular expressions in ETEX, there should be no literal spaces in the argument to \regexp. Please use escape code equivalents if spaces are needed. For example, this example, if using \regexp, should be:

Here, we have used the hexadecimal escape sequence ' $\x20$ ' in place of literal spaces in the replacement strings.

```
\DeclareSourcemap{
  \maps[datatype=bibtex] {
```

Only applies to entries with an author field matching 'Doe,'. First the author field is copied to both the shortauthor and sortname fields, overwriting them if they already exist. Then, these two new fields are modified to canonicalise a particular name, which presumably has some variants in the data source.

```
\DeclareSourcemap{
  \maps[datatype=bibtex]{
    \map[overwrite]{
      \step[fieldsource=verba, final]
      \step[fieldset=verbb, fieldvalue=/, append]
      \step[fieldset=verbb, origfieldval, append]
      \step[fieldsource=verbb, final]
      \step[fieldset=verbc, fieldvalue=/, append]
      \step[fieldset=verbc, origfieldval, append]
    }
}
```

This example demonstrates the sequential nature of the step processing and the append option. If an entry has a verba field then first, a forward slash is appended to the verbb field. Then, the contents of verba are appended to the verbb field. A slash is then appended to the verbc field and the contents of verbb are appended to the verbc field.

```
\DeclareSourcemap{
  \maps[datatype=bibtex] {
    \map[overwrite] {
     \step[fieldset=autourl, fieldvalue={http://scholar.google.com/scholar?com/scholar?com/scholar?com/scholar?com/scholar?com/scholar?com/scholar?com/scholar?com/scholar?com/scholar?com/scholar?com/scholar?com/scholar?com/scholar?com/scholar?com/scholar?com/scholar?com/scholar?com/scholar?com/scholar?com/scholar.com/scholar?com/scholar.com/scholar?com/scholar.com/scholar?com/scholar.com/scholar.com/scholar.com/scholar.com/scholar.com/scholar.com/scholar.com/scholar.com/scholar.com/scholar.com/scholar.com/scholar.com/scholar.com/scholar.com/scholar.com/scholar.com/scholar.com/scholar.com/scholar.com/scholar.com/scholar.com/scholar.com/scholar.com/scholar.com/scholar.com/scholar.com/scholar.com/scholar.com/scholar.com/scholar.com/scholar.com/scholar.com/scholar.com/scholar.com/scholar.com/scholar.com/scholar.com/scholar.com/scholar.com/scholar.com/scholar.com/scholar.com/scholar.com/scholar.com/scholar.com/scholar.com/scholar.com/scholar.com/scholar.com/scholar.com/scholar.com/scholar.com/scholar.com/scholar.com/scholar.com/scholar.com/scholar.com/scholar.com/scholar.com/scholar.com/scholar.com/scholar.com/scholar.com/scholar.com/scholar.com/scholar.com/scholar.com/scholar.com/scholar.com/scholar.com/scholar.com/scholar.com/scholar.com/scholar.com/scholar.com/scholar.com/scholar.com/scholar.com/scholar.com/scholar.com/scholar.com/scholar.com/scholar.com/scholar.com/scholar.com/scholar.com/scholar.com/scholar.com/scholar.com/scholar.com/scholar.com/scholar.com/scholar.com/scholar.com/scholar.com/scholar.com/scholar.com/scholar.com/scholar.com/scholar.com/scholar.com/scholar.com/scholar.com/scholar.com/scholar.com/scholar.com/scholar.com/scholar.com/scholar.com/scholar.com/scholar.com/scholar.com/scholar.com/scholar.com/scholar.com/scholar.com/scholar.com/scholar.com/scholar.com/scholar.com/scholar.com/scholar.com/scholar.com/scholar.com/scholar.com/scholar.com/scholar.com/scholar.com/scholar.com/scholar.com/scholar.com/scholar.com/scholar.co
```

```
\step[fieldset=autourl, fieldvalue={"+author:}, append]
\step[fieldsource=author, match=\regexp{\A([^,]+)\s*,}]
\step[fieldset=autourl, fieldvalue={$1}, append]
\step[fieldset=autourl, fieldvalue={&as_ylo=}, append]
\step[fieldsource=year]
\step[fieldset=autourl, origfieldval, append]
\step[fieldset=autourl, fieldvalue={&as_yhi=}, append]
\step[fieldset=autourl, origfieldval, append]
}
}
```

This example assumes you have created a field called autourl using the datamodel macros from § 4.5.3 in order to hold, for example, a Google Scholar query URL autocreated from elements of the entry. The example progressively extracts information from the entry, constructing the URL as it goes. It demonstrates that it is possible to refer to parenthetical matches from the most recent match in any following fieldvalue which allows extracting the lastname from the author, assuming a 'last, first' format. The resulting field could then be used as a hyperlink from, for example, the title of the work in the bibliography.

```
\DeclareSourcemap{
  \maps[datatype=bibtex] {
    \map{
     \step[fieldsource=title, match={A Title}, final]
     \step[entrynull]
     }
  }
}
```

Any entry with a title field matching 'A Title' will be completely ignored.

```
\DeclareSourcemap{
  \maps[datatype=bibtex] {
      \map{
        \pernottype{book}
        \pernottype{article}
      \step[entrynull]
      }
    }
}
```

Any entry which is not a @book or @article will be ignored.

```
\DeclareSourcemap{
```

Here, a clone of an entry from the specified data source will be created. The entry key of the clone will be the same as the original but prefixed by the value of the entryclone parameter. The cloned entry would still need to be cited in the document using its new entry key. This type of mapping step should be used with care as it may produce labelling problems in authoryear styles which use, for example, extrayear. One use case is for numeric styles which contain multiple bibliographies containing the same entry. In this case, you may need different bibliography number labeld for the same entry and this is very tricky when there is only one entry which needs different labels. Creating clones with different entry keys solves this problem.

### 4.5.3 数据模型规范 Data Model Specification

Biber only

The data model which Biblatex uses consists of four main elements:

- Specification of valid Entrytypes
- Specification of valid Fields along with their type, datatype and any special flags
- Specification of which Fields are valid in which Entrytypes
- Specification of constraints which can be used to validate data against the data model

The default data model is defined in the core Biblatex file blx-dm.def using the macros described in this section. The default data model is described in detail in § 2. The data model is used internally by Biblatex and also by the backends. The data model for the BibTeX backend is hard-coded and cannot be changed. Changing the data model is only supported for the Biber backend. In practice, changing the data model means that you can define the entrytypes and fields for your datasources and validate your data against the data model. Naturally, this is not much use unless your style supports any new entrytypes or fields and it raises issues of portability between styles (although this can be mitigated by using the dynamic data modification functionality described in § 4.5.2).

Validation against the data model means that after mapping your data sources into the data model, Biber (using its --validate datamodel option) can check:

• Whether all entrytypes are valid entrytypes

- Whether all fields are valid fields for their entrytype
- · Whether the fields obey various constraints on their format which you specify

Redefining the data model can be done in several places. Style authors can create a .dbx file which contains the data model macros required and this will be loaded automatically when using the Biblatex package style option by looking for a file named after the style with a .dbx extension (just like the .cbx and .bbx files for a style). If the style option is not used but rather the citestyle and bibstyle options, then the package will try to load .dbx files called 'citestyle'.dbx and 'bibstyle'.dbx. Alternatively, the name of the data model file can be different from any of the style option names by specifying the name (without .dbx extension) to the package datamodel option. After loading the style data model file, Biblatex then loads, if present, a users biblatex-dm.cfg which should be put somewhere Biblatex can find it, just like the main configuration file biblatex.cfg. To summarise, the data model is determined by adding to the data model from each of these locations, in order:

It is not possible to add to a loaded data model by using the macros below in your preamble as the preamble is read after Biblatex has defined critical internal macros based on the data model. If any data model macro is used in a document, it will be ignored and a warning will be generated. The data model is defined using the following macros:

```
\DeclareDatamodelEntrytypes[\langle options \rangle] \{ \langle entrytypes \rangle \}
```

Biber only

Declares the comma-separated list of *(entrytypes)* to be valid entrytypes in the data model. As usual in TeX csv lists, make sure each element is immediately followed by a comma or the closing brace—no extraneous whitespace.

```
skipout=true, false default: false
```

This entrytype is not output to the .bbl. Typically used for special entrytypes which are processed and consumed by the backend such as @xdata.

```
\DeclareDatamodelFields[\langle options \rangle] \{\langle fields \rangle\}
```

Biber only

Declares the comma-separated list of  $\langle fields \rangle$  to be valid fields in the data model with associated comma-separated  $\langle options \rangle$ . The  $\langle type \rangle$  and  $\langle datatype \rangle$  options are mandatory. All valid  $\langle options \rangle$  are:

```
type=\(\)field type\\
```

Set the type of the field as described in § 2.2.1. Is typically 'field' or 'list'.

```
format=\langle field format\rangle
```

Any special format of the field. Normally unspecified but can take the value 'xsv' which tells Biber that this field has a separated values format. The exact separator can be controlled with the Biber option xsvsep and defaults to the expected comma surrounded by optional whitespace.

```
datatype=\langle field datatype \rangle
```

Set the datatype of the field as described in § 2.2.1. For example, 'name' or 'literal'.

```
nullok=true, false default: false
```

The field is allowed to be defined but empty.

```
skipout=true, false default: false
```

The field is not output to the .bbl and is therefore not present during Biblatex style processing. As usual in TeX csv lists, make sure each element is immediately followed by a comma or the closing brace—no extraneous whitespace.

```
label=true, false default: false
```

The field can be used as a label in a bibliography or bibliography list. Specifying this causes Biblatex to create several helper macros for the field so that there are some internal lengths and headings etc. defined.

```
\DeclareDatamodelEntryfields[\langle entrytypes\rangle] {\langle fields \rangle}
```

Biber only

Declares that the comma-separated list of  $\langle fields \rangle$  is valid for the comma-separated list of  $\langle entrytypes \rangle$ . If  $\langle entrytypes \rangle$  is not given, the fields are valid for all entrytypes. As usual in TeX csv lists, make sure each element is immediately followed by a comma or the closing brace—no extraneous whitespace.

```
\DeclareDatamodelConstraints[\langle entrytypes\rangle] {\langle specification \rangle}
```

Biber only

If a comma-separated list of  $\langle entrytypes \rangle$  is given, the constraints apply only to those entrytypes. The  $\langle specification \rangle$  is an undelimited list of \constraint directives which specify a constraint. Spaces, tabs, and line endings may be used freely to visually arrange the  $\langle specification \rangle$ . Blank lines are not permissible.

```
\constraint[\langle type=constrainttype \rangle ] {\langle elements \rangle }
```

Specifies a constraint of type  $\langle constraint type \rangle$ . Valid constraint types are:

```
type=data, mandatory, conditional
```

Constraints of type 'data' put restrictions on the value of a field. Constraints of type 'mandatory' specify which fields or combinations of fields an entrytype should have. Constraints of type 'conditional' allow more sophisticated conditional and quantified field constraints.

```
datatype=integer, isbn, issn, ismn, date, pattern
```

For constraints of type  $\langle data \rangle$ , constrain field values to be the given datatype.

```
rangemin=\langle num \rangle
```

For constraints of  $\langle type \rangle$  'data' and  $\langle datatype \rangle$  'integer', constrain field values to be at least  $\langle num \rangle$ .

```
rangemax = \langle num \rangle
```

For constraints of  $\langle type \rangle$  'data' and  $\langle datatype \rangle$  'integer', constrain field values to be at most  $\langle num \rangle$ .

```
pattern=\(patt\)
```

For constraints of  $\langle type \rangle$  'data' and  $\langle datatype \rangle$  'pattern', constrain field values to match regular expression pattern  $\langle patt \rangle$ . It is best to wrap any regular expression in the macro \regexp, see § 4.5.2.

A \constraint macro may contain any of the following:

```
\constraintfieldsor{\langle fields \rangle}
```

For constraints of  $\langle type \rangle$  'mandatory', specifies that an entry must contain a boolean OR of the \constraintfields.

```
\constraintfieldsxor{\langle fields\rangle}
```

For constraints of  $\langle type \rangle$  'mandatory', specifies that an entry must contain a boolean XOR of the \constraintfields.

```
\arrange \
```

For constraints of  $\langle type \rangle$  'conditional', specifies a quantified set of \constraintfields which must be satisfied before the \consequent of the constraint is checked.  $\langle quantspec \rangle$  should have one of the following values:

```
quantifier=all, one, none
```

Specifies how many of the \constrainfield's inside the \antecedent have to be present to satisfy the antecedent of the conditional constraint.

```
\consequent[\langle quantifier=quantspec \rangle] \{\langle fields \rangle\}
```

For constraints of  $\langle type \rangle$  'conditional', specifies a quantified set of \constraintfields which must be satisfied if the preceding \antecedent of the constraint was satisfied.  $\langle quantspec \rangle$  should have one of the following values:

```
quantifier=all, one, none
```

Specifies how many of the \constraintfield's inside the \consequent have to be present to satisfy the consequent of the conditional constraint.

```
\constraintfield{\langle field \rangle}
```

For constraints of  $\langle type \rangle$  'data', the constraint applies to this  $\langle field \rangle$ . For constraints of  $\langle type \rangle$  'mandatory', the entry must contain this  $\langle field \rangle$ .

The data model declaration macros may be used multiple times as they append to the previous definitions. In order to replace, change or remove existing definitions (such as the default model which is loaded with Biblatex), you should reset (clear) the current definition and then set what you want using the following macros. Typically, these macros will be the first things in any biblatex-dm.cfg file:

#### \ResetDatamodelEntrytypes

Clear all data model entrytype information.

#### \ResetDatamodelFields

Clear all data model field information.

#### \ResetDatamodelEntryfields

Clear all data model fields for entrytypes information.

#### \ResetDatamodelConstraints

Clear all data model fields Constraints information.

\constraint[type=mandatory] {

Here is an example of a simple data model. Refer to the core Biblatex file blx-dm.def for the default data model specification.

```
ResetDatamodelEntrytypes
ResetDatamodelFields
ResetDatamodelEntryfields
ResetDatamodelConstraints

DeclareDatamodelEntrytypes{entrytype1, entrytype2}

DeclareDatamodelFields[type=field, datatype=literal]{field1,field2,field3,f:
DeclareDatamodelEntryfields{field1}
DeclareDatamodelEntryfields[entrytype1]{field2,field3}
DeclareDatamodelEntryfields[entrytype2]{field2,field3,field4}

DeclareDatamodelConstraints[entrytype1]{
   \constraint[type=data, datatype=integer, rangemin=3, rangemax=10]{
   \constraintfield{field1}
}
```

```
\constraintfield{field1}
\constraintfieldsxor{
    \constraintfield{field2}
    \constraintfield{field3}
}
}

DeclareDatamodelConstraints{
  \constraint[type=conditional]{
    \antecedent[quantifier=none]{
     \constraintfield{field2}
}
  \consequent[quantifier=all]{
    \constraintfield{field3}
    \constraintfield{field4}
}
}

constraintfield{field4}
}
```

## This model specifies:

- Clear the default data model completely
- Two valid entry types @entrytype1 and @entrytype2
- · Four valid literal field fields
- field1 is valid for all entrytypes
- field2 and field3 are valid for entrytype1
- field2, field3 and field4 are valid for @entrytype2
- For @entrytype1:
  - field1 must be an integer between 3 and 10
  - field1 must be present
  - One and only one of field2 or field3 must be present
- For any entrytype, if field2 is not present, field3 and field4 must be present

## 4.5.4 标签 Labels

字母顺序制样式使用一个标签来区分参考文献条目。这个标签由条目的内容使用一个描述怎么构建标签的模板构建。该模板可以全局自定义或者分条目类型定义。标签的自定义需要用 Biber 后端而不能用其它后端。

Biber only

Defines the alphabetic label template for the given entrytypes. If no entrytypes are specified in the first argument, then the global label template is defined. The  $\langle specification \rangle$  is an undelimited list of \labelelement directives which specify the elements used to build the label. Spaces, tabs, and line endings may be used freely to visually arrange the  $\langle specification \rangle$ . Blank lines are not permissible. This command may only be used in the preamble.

```
\labelelement{\langle elements\rangle}
```

Specifies the elements used to build the label. The *(elements)* are an undelimited list of \field or \literal commands which are evaluated in the order in which they are given. The first \field or \literal which expands to a non-empty string is used as the \labelelement expansion and the next \labelelement, if any, is then processed.

If  $\langle field \rangle$  is non-empty, use it as the current label \labelelement, subject to the options below. Useful values for  $\langle field \rangle$  are typically the name list type fields, date fields, and title fields. You may also use the 'citekey' pseudo-field to specify the citation key as part of the label. Name list fields are treated specially and the options which take substrings of the  $\langle field \rangle$  to use in the \labelelement are applied to the lastname of every name in a name list (see below).

```
final=true, false default: false
```

This option marks a \field directive as the final one in the  $\langle specification \rangle$ . If the  $\langle field \rangle$  is non-empty, then this field is used for the label and the remainder of the  $\langle specification \rangle$  will be ignored. The short form final is equivalent to final=true.

```
lowercase=true, false default: false
```

Forces the label part derived from the field to lowercase. By default, the case is taken from the field source and not modified.

```
strwidth=\(integer\) default: 1
```

The number of characters of the  $\langle field \rangle$  to use. For name list fields, if useprefix=true, the first character of the name prefix is prepended to the substring.

```
strside=left, right default: left
```

The side of the string from which to take the strwidth number of characters.

```
padside=left, right default: right
```

Side to pad the label part when using the padchar option. Only for use with fixed-width label strings (strwidth).

```
padchar=(character)
```

If present, pads the label part on the padside side with the specified character to the length of strwidth. Only for use with fixed-width label strings (strwidth).

```
uppercase=true, false default: false
```

Forces the label part derived from the field to uppercase. By default, the case is taken from the field source and not modified.

```
varwidth=true, false default: false
```

Use a variable width, left-side substring of characters from the  $\langle field \rangle$  (each lastname in name list fields). The length of the string is determined by the minimum length needed to disambiguate the substring from all other  $\langle field \rangle$  elements in the same position in the label. For name list fields, this means that each name substring is disambiguated from all other name substrings which occur in the same position in the name list (see examples below). This option overrides strwidth if both are used. The short form varwidth is equivalent to varwidth=true. For name list fields, if useprefix=true, the first character of the name prefix is prepended to the substring.

```
varwidthnorm=true, false default: false
```

As varwidth but will force the disambiguated substrings for the  $\langle field \rangle$  to be the same length as the longest disambiguated substring. This can be used to regularise the format of the labels if desired. This option overrides strwidth if both are used. The short form varwidthnorm is equivalent to varwidthnorm=true.

```
varwidthlist=true, false default: false
```

Alternative method of automatic label disambiguation where the field as a whole is disambiguated from all other fields in the same label position. For non-name list fields, this is equivalent to varwidth. For name list fields, names in a name list are not disambiguated from other names in the same position in their name lists but instead the entire name list is disambiguated as a whole from other name lists (see examples below). This option overrides strwidth if both are used. The short form varwidthlist is equivalent to varwidthlist=true. For name list fields, if useprefix=true, the first character of the name prefix is prepended to the substring.

```
strwidthmax=\langle integer\rangle
```

When using varwidth, this option sets a limit (in number of characters) on the length of variable width substrings. This option can be used to regularise the label.

```
strfixedcount=\(\int \text{integer}\) default: 1
```

When using varwidthnorm, there must be at least strfixedcount disambiguated substrings with the same, maximal length to trigger the forcing of all disambiguated substrings to this same maximal length.

```
compound=true, false default: false
```

For static (non-varwidth) disambiguation, treat lastname name components separated by whitespace or hyphens (compound last names) as separate names for label generation. This means that when forming a label out of, for example the surname 'Ballam Forsyth' with a 1 character, left-side substring, this name would give 'BF' with compound=true and 'B' with compound=false. The short form compound is equivalent to compound=true.

```
ifnames=\(integer\)
```

Only use this \field specification if it is a name list field with ifnames names in it. This allows a \labelelement to be conditionalised on name length (see below).

```
names=(integer)
```

By default, for name list fields, the number of names considered when building the label obeys the maxalphanames/minalphanames truncation. This option can be used to override this with an explicit upper limit of how many names to consider. This is useful if you have some very long name lists which might result in a very long label.

```
form=original, translated, romanised, uniform default: original
Specifies the script variant of a field, if the datasource you are using supports this.
```

```
lang='language specifier' default: none
```

Specifies the babel/polyglossia language variant of a field if the datasource you are using supports this. The default, if no  $\langle lang \rangle$  option is set, this means to use the field variant in the datasource which has no explicit language defined.

```
\literal{\langle characters\rangle}
```

Insert the literal  $\langle characters \rangle$  into the label at this point.

Note that the template for labels can be defined per-type and you should be aware of this when using the automatically disambiguated label functionality. Disambiguation is not per-type as this might lead to ambiguity due to different label formats for different types being isolated from each others disambiguation process. Normally, you will want to use very different label formats for different types to make the type obvious by the label.

Here are some examples. The default global Biblatex alphabetic label template is defined below. Firstly, shorthand has final=true and so if there is a shorthand field, it is used as the label and nothing more of the template is considered. Next, the label field is used as the first label element if it exists. Otherwise, if there is only one name (ifnames=1) in the labelname list, then three characters from the left side of the lastname in the labelname are used as the first label element. If the labelname has more than one name in it, one character from the left side of each lastname is used as the first label element. The second label element consists of 2 characters from the right side of the year field.

```
\DeclareLabelalphaTemplate{
  \labelelement{
    \field[final] {shorthand}
```

```
\field{label}
  \field[strwidth=3,strside=left,ifnames=1]{labelname}
  \field[strwidth=1,strside=left]{labelname}
}
\labelelement{
  \field[strwidth=2,strside=right]{year}
}
```

To get an idea of how the label automatic disambiguation works, consider the following author lists:

```
Agassi, Chang, Laver (2000)
Agassi, Connors, Lendl (2001)
Agassi, Courier, Laver (2002)
Borg, Connors, Edberg (2003)
Borg, Connors, Emerson (2004)
```

### Assuming a template declaration such as:

```
\DeclareLabelalphaTemplate{
   \labelelement{
    \field[varwidth] {labelname}
   }
}
```

## Then the labels would be:

```
Agassi, Chang, Laver [AChLa]
Agassi, Connors, Lendl [AConLe]
Agassi, Courier, Laver [ACouLa]
Borg, Connors, Edberg [BConEd]
Borg, Connors, Emerson [BConEm]
```

## With normalised variable width labels defined:

```
\DeclareLabelalphaTemplate{
   \labelelement{
     \field[varwidthnorm] {labelname}
   }
}
```

You would get the following as the substrings of names in each position are extended to the length of the longest substring in that same position:

```
Agassi, Chang, Laver [AChaLa]
Agassi, Connors, Lendl [AConLe]
Agassi, Courier, Laver [ACouLa]
Borg, Connors, Edberg [BConEd]
Borg, Connors, Emerson [BConEm]
```

With a restriction to two characters for the name components of the label element defined like this:

```
\DeclareLabelalphaTemplate{
   \labelelement{
    \field[varwidthnorm, strwidthmax=2] {labelname}
   }
}
```

This would be the result (note that the individual lastname label parts are no longer unambiguous):

```
Agassi, Chang, Laver [AChLa]
Agassi, Connors, Lendl [ACoLe]
Agassi, Courier, Laver [ACoLa]
Borg, Connors, Edberg [BCoEd]
Borg, Connors, Emerson [BCoEm]
```

Alternatively, you could choose to disambiguate the name lists as a whole with:

```
\DeclareLabelalphaTemplate{
   \labelelement{
     \field[varwidthlist] {labelname}
   }
}
```

Which would result in:

```
Agassi, Chang, Laver [AChL]
Agassi, Connors, Lendl [ACoL]
Agassi, Courier, Laver [ACL]
Borg, Connors, Edberg [BCEd]
Borg, Connors, Emerson [BCE]
```

Perhaps you only want to consider at most two names for label generation but disambiguate at the whole name list level:

```
\DeclareLabelalphaTemplate{
   \labelelement{
     \field[varwidthlist,names=2]{labelname}
   }
}
```

#### Which would result in:

```
Agassi, Chang, Laver [ACh+]
Agassi, Connors, Lendl [ACo+]
Agassi, Courier, Laver [AC+]
Borg, Connors, Edberg [BC+a]
Borg, Connors, Emerson [BC+b]
```

In this last example, you can see \labelalphaothers has been appended to show that there are more names. The last two labels now require disambiguating with \extraalpha as there is no way of disambiguating this label name list with only two names.

Finally, here is an example using multiple label elements:

```
\DeclareLabelalphaTemplate{
  \labelelement{
    \field[varwidthlist] {labelname}
}
  \labelelement{
    \literal{-}
}
  \labelelement{
    \field[strwidth=3,strside=right] {labelyear}
}
}
```

#### Which would result in:

```
Agassi, Chang, Laver [AChL-000]
Agassi, Connors, Lendl [AConL-001]
Agassi, Courier, Laver [ACouL-002]
Borg, Connors, Edberg [BCEd-003]
Borg, Connors, Emerson [BCEm-004]
```

Here is another rather contrived example showing that you don't need to specially quote LaTeX special characters (apart from '%', obviously) when specifying padding characters and literals:

```
\DeclareLabelalphaTemplate{
   \labelelement{
    \literal{>}
   }
   \labelelement{
    \literal{\%}
   }
}
```

```
\labelelement{
    \field[strwidth=4, padchar= ]{labelname}
  \labelelement{
    \field[strwidth=3, padchar=&, padside=left]{title}
  }
  \labelelement{
    \field[strwidth=2,strside=right]{year}
  }
}
which given:
@Book{test,
  author
           = \{XXX YY\},
  title
           = \{T\}
            = \{2007\},
  year
}
```

would resulting a label looking like this:

```
[>%YY &&T07]
```

## 4.5.5 排序 Sorting

In addition to the predefined sorting schemes discussed in § 3.5, it is possible to define new ones or modify the default definitions. The sorting process may be customized further by excluding certain fields from sorting on a per-type basis and by automatically populating the presort field on a per-type basis. Note that custom sorting schemes require Biber. They will not work with any other backend.

```
\DeclareSortingScheme [\langle options \rangle] \{\langle name \rangle\} \{\langle specification \rangle\}
```

Biber only

Defines the sorting scheme  $\langle name \rangle$ . The  $\langle name \rangle$  is the identifier passed to the sorting option (§ 3.1.2.1) when selecting the sorting scheme. The \DeclareSortingScheme command supports the following optional arguments:

```
locale=\locale\
```

The locale for the sorting scheme which then overrides the global sorting locale in the sortlocale option discussed in § 3.1.2.1.

The  $\langle specification \rangle$  is an undelimited list of \sort directives which specify the elements to be considered in the sorting process. Spaces, tabs, and line endings may be used freely to visually arrange the  $\langle specification \rangle$ . Blank lines are not permissible. This command may only be used in the preamble.

```
\sort{\left\(\left\)}
```

Specifies the elements considered in the sorting process. The *(elements)* are an undelimited list of \field, \literal, and \citeorder commands which are evaluated in the order in which they are given. If an element is defined, it is added to the sort key and the sorting routine skips to the next \sort directive. If it is undefined, the next element is evaluated. Since literal strings are always defined, any \literal commands should be the sole or the last element in a \sort directive. The \sort command supports the following optional arguments:

```
locale = \langle locale \rangle
```

Override the locale used for sorting at the level of a particular set of sorting elements. If specified, the locale overrides the locale set at the level of \DeclareSortingScheme and also the global setting. See also the discussion of the global sorting locale option sortlocale in § 3.1.2.1.

```
direction=ascending, descending default: ascending
```

The sort direction, which may be either ascending or descending. The default is ascending order.

```
final=true, false default: false
```

This option marks a \sort directive as the final one in the  $\langle specification \rangle$ . If one of the  $\langle elements \rangle$  is available, the remainder of the  $\langle specification \rangle$  will be ignored. The short form final is equivalent to final=true.

```
sortcase=true, false
```

Whether or not to sort case-sensitively. The default setting depends on the global sortcase option.

```
sortupper=true, false
```

Whether or not to sort in 'uppercase before lowercase' (true) or 'lowercase before uppercase' order (false). The default setting depends on the global sortupper option.

```
field[\langle key=value, ... \rangle] \{\langle field \rangle\}
```

The \field element adds a  $\langle field \rangle$  to the sorting specification. If the  $\langle field \rangle$  is undefined, the element is skipped. The \field command supports the following optional arguments:

```
padside=left, right default: left
```

Pads a field on the left or right side using padchar so that its width is padwidth. If no padding option is set, no padding is done at all. If any padding option is specified, then padding is performed and the missing options are assigned built-in default values. If padding and substring matching are both specified, the substring match is performed first. Padding is particularly useful with numeric fields. For example, the command

```
\field[padside=left,padwidth=2,padchar=0] {volume}
```

will pad the volume field with leading zeros to a width of two characters. This way, volumes are sorted by numeric value (01/02/11/12) rather than in alphabetic order (1/11/12/2).

```
padwidth=\(integer\)
                                                                           default: 4
```

The target width in characters.

```
default: 0
padchar=(character)
```

The character to be used when padding the field.

```
strside=left, right
                                                           default: left
```

Performs a substring match on the left or right side of the field. The number of characters to match is specified by the corresponding strwidth option. If no substring option is set, no substring matching is performed at all. If any substring option is specified, then substring matching is performed and the missing options are assigned built-in default values. If padding and substring matching are both specified, the substring match is performed first.

```
strwidth=\(integer\)
                                                                           default: 4
```

The number of characters to match.

```
\literal { \langle string \rangle }
```

The \literal element adds a literal  $\langle string \rangle$  to the sorting specification. This is useful as a fallback if some fields are not available.

\citeorder The \citeorder element has a special meaning. It requests a sort based on the lexical order of the actual citations. For entries cited within the same citation command like:

```
\cite{one, two}
```

there is a distinction between the lexical order and the semantic order. Here "one" and "two" have the same semantic order but a unique lexical order. The semantic order only matters if you specify further sorting to disambiguate entries with the same semantic order. For example, this is the definition of the none sorting scheme:

```
\DeclareSortingScheme{none}{
  \sort{\citeorder}
}
```

This sorts the bibliography purely lexically by the order of the keys in the citation commands. In the example above, it sorts "one" before "two". However, suppose that you consider "one" and "two" to have the same order (semantic order) since they are cited at the same time and want to further sort these by year. Suppose "two" has an earlier year than "one":

```
\DeclareSortingScheme{noneyear}{
  \sort{\citeorder}
  \sort{year}
}
```

This sorts "two" before "one", even though lexically, "one" would sort before "two". This is possible because the semantic order can be disambiguated by the further sorting on year. With the standard none sorting scheme, the lexical order and semantic order are identical because there is nothing further to disambiguate them. This means that you can use \citeorder just like any other sorting specification element, choosing how to further sort entries cited at the same time (in the same citation command).

Here are some examples of sorting schemes. In the first example, we define a simple name/title/year scheme. The name element may be either the author, the editor, or the translator. Given this specification, the sorting routine will use the first element which is available and continue with the title. Note that the options use<name> options are considered automatically in the sorting process:

```
\DeclareSortingScheme{sample}{
  \sort{
    \field{author}
    \field{editor}
    \field{translator}
}
\sort{
    \field{title}
}
\sort{
    \field{year}
}
```

In the next example, we define the same scheme in a more elaborate way, considering special fields such as presort, sortkey, sortname, etc. Since the sortkey field specifies the master sort key, it needs to override all other elements except for presort. This is indicated by the final option. If the sortkey field is available, processing will stop at this point. If not, the sorting routine continues with the next \sort directive. This setup corresponds to the default definition of the nty scheme:

```
\DeclareSortingScheme{nty}{
  \sort{
    \field{presort}
  }
  \sort[final]{
```

```
\field{sortkey}
  }
  \sort{
    \field{sortname}
    \field{author}
    \field{editor}
    \field{translator}
    \field{sorttitle}
    \field{title}
  }
  \sort{
    \field{sorttitle}
    \field{title}
  }
  \sort{
    \field{sortyear}
    \field{year}
  }
}
```

Finally, here is an example of a sorting scheme which overrides the global sorting locale and additionally overrides again when sorting by the <code>origtitle</code> field. Note the use in the scheme-level override of a babel/polyglossia language name instead of a real locale identifier. Biber will map this to a suitable, real locale identifier (in this case, <code>sv SE</code>):

```
\DeclareSortingScheme[locale=swedish] {custom} {
    \sort{
        \field{sortname}
        \field{author}
        \field{editor}
        \field{translator}
        \field{sorttitle}
        \field{title}
}
\sort[locale=de_DE_phonebook] {
        \field{origtitle}
}
```

```
\verb|\DeclareSortExclusion{| \langle \textit{entrytype}, ... \rangle } { \langle \textit{field}, ... \rangle }
```

Biber only

Specifies fields to be excluded from sorting on a per-type basis. The  $\langle entrytype \rangle$  argument and the  $\langle field \rangle$  argument may be a comma-separated list of values. A blank  $\langle field \rangle$ 

argument will clear all exclusions for this  $\langle entrytype \rangle$ . This command may only be used in the preamble.

```
\DeclarePresort[\langle entrytype, ... \rangle] \{\langle string \rangle\}
```

Biber only

Specifies a string to be used to automatically populate the presort field of entries without a presort field. The presort may be defined globally or on a per-type basis. If the optional  $\langle entrytype \rangle$  argument is given, the  $\langle string \rangle$  applies to the respective entry type. If not, it serves as the global default value. Specifying an  $\langle entrytype \rangle$  in conjunction with a blank  $\langle string \rangle$  will clear the type-specific setting. The  $\langle entrytype \rangle$  argument may be a comma-separated list of values. This command may only be used in the preamble.

# 4.5.6 参考文献表过滤器 Bibliography List Filters

Biber only

When using customisable bibliography lists (See § 3.6.4), usually one wants to return in the .bbl only those entries which have the particular fields which the bibliography list is summarising. For example, when printing a normal list of shorthands, you want the list returned by Biber in the .bbl to contain only those entries which have a shorthand field. This is accomplished by defining a bibliography list filter using the \DeclareBiblistFilter command. This differs from the filters defined using \defbibfilter (see § 3.6.10) since the filters defined by \defbibfilter run inside Biblatex after the .bbl has been generated. In addition, bibliography lists in the .bbl do not contain entry data, only the citation keys for the entries and so no filtering by Biblatex using \defbibfilter is possible for bibliography lists.

```
\DeclareBiblistFilter{\( name \) \} \{\( specification \) \}
```

Biber only

Defines a bibliography list filter with  $\langle name \rangle$ . The  $\langle specification \rangle$  consists of one or more \filter or \filteror macros, all of which must be satisfied for the entry to pass the filter:

```
\left\langle \text{filter} \left\langle \left\langle type \right\rangle \right\rangle \right\rangle \left\langle \left\langle filter \right\rangle \right\rangle
```

Filter entries according to the  $\langle type \rangle$  and  $\langle filter \rangle$ .  $\langle type \rangle$  can be one of:

**type/nottype** Entry is/is not of entrytype \( \filter \)

**subtype/notsubtype** Entry is/is not of subtype (*filter*)

**keyword/notkeyword** Entry has/does not have keyword (filter)

**field/notfield** Entry has/does not have a field called \( filter \)

```
\left\langle \text{filters} \right\rangle \left\langle \left\langle \text{filters} \right\rangle \right\rangle
```

A wrapper around one or more  $\filter$  commands specifying that they form a disjunctive set, i.e. any one of the  $\langle filters \rangle$  must be satisfied.

Fields in the datamodel which are marked as 'Label fields' (see § 4.5.3) automatically have a filter defined for them with the same name and which filters out any entries which do no contain the field. For example, Biblatex automatically generates a filter for the shorthand field:

```
\DeclareBiblistFilter{shorthand}{
  \filter[type=field,filter=shorthand]
}
```

### 4.5.7 控制姓名首字母生成 Controlling Name Initials Generation

Generating initials for name parts from a given name involves some difficulties when you have names with prefixes, diacritics, hyphens etc. Often, you want to ignore things like prefixes when generating initials so that the initials for "al-Hasan" is just "H" instead of "a-H". This is tricky when you also have names like "Ho-Pun" where you want the initials to be "H-P", for example.

```
\DeclareNoinit{\langle specification\rangle}
```

Biber only

Defines regular expressions to strip from names before generating initials. The  $\langle specification \rangle$  is an undelimited list of \noinit directives which specify the regular expressions to remove from the name. Spaces, tabs and line endings may be used freely to visually arrange the  $\langle specification \rangle$ . Blank lines are not permissible. This command may only be used in the preamble.

```
\noinit{\langle regexp\rangle}
```

Any number of \noinit commands can be given each of which specifies to remove the \( \textit{regexp} \) from the copy of the name which the initials generation system sees. Since regular expressions usually contain special characters, it is best to enclose them in the provided \regexp macro as shown—this will pass the expression through to Biber correctly.

If there is no \DeclareNoinit specification, Biber will default to:

```
\DeclareNoinit{
    % strip lowercase prefixes like 'al-' when generating initials from names
    \noinit{\regexp{\b\p{L1}{2}\p{Pd}}}
    % strip some common diacritics when generating initials from names
    \noinit{\regexp{[\x{2bf}\x{2018}]}}
}
```

This Biber default strips a couple of diacritics and also strips lowercase prefixes from names before generating initials.

## 4.5.8 排序微调 Fine Tuning Sorting

对排序微调是很有用的,它可以忽略一些特殊域的某些部分。

```
\DeclareNosort { \langle specification \rangle }
```

Biber only

Defines regular expressions to strip from particular fields or types of fields when sorting. The  $\langle specification \rangle$  is an undelimited list of  $\setminus nosort$  directives which specify the regular expressions to remove from particular fields or type of field. Spaces, tabs and line endings may be used freely to visually arrange the  $\langle specification \rangle$ . Blank lines are not permissible. This command may only be used in the preamble.

```
\nosort {\langle field \ or \ field \ type \rangle} {\langle regexp \rangle}
```

Any number of \nosort commands can be given each of which specifies to remove the  $\langle regexp \rangle$  from the  $\langle field \rangle$  or  $\langle field \ type \rangle$ . A  $\langle field \ type \rangle$  is simple a convenience grouping of semantically similar fields from which you might want to remove a regexp. Table 9 shows the available field types. Since regular expressions usually contain special characters, it is best to enclose them in the provided \regexp macro as shown—this will pass the expression through to Biber correctly.

If there is no \DeclareNosort specification, Biber will default to:

```
\DeclareNosort{
    % strip prefixes like 'al-' when sorting names
    \nosort{type_names}{\regexp{\A\p{L}{2}\p{Pd}}}
    % strip some diacritics when sorting names
    \nosort{type_names}{\regexp{[\x{2bf}\x{2018}]}}
}
```

This Biber default strips a couple of diacritics and also strips prefixes from names when sorting. Suppose you wanted to ignore "The" at the beginning of a title field when sorting:

```
\DeclareNosort{
  \nosort{title}{\regexp{\AThe\s+}}
}
```

Or if you wanted to ignore "The" at the beginning of any title field:

```
\DeclareNosort{
   \nosort{type_title}{\regexp{\AThe\s+}}
}
```

Field Type	Fields
type_name	author
	afterword
	annotator
	bookauthor
	commentator
	editor
	editora
	editorb
	editorc
	foreword
	holder
	introduction
	namea
	nameb
	namec
	shortauthor
	shorteditor
	translator
type_title	booktitle
	eventtitle
	issuetitle
	journaltitle
	maintitle
	origtitle
	title

Table 9: Field types for \nosort

## 4.5.9 特殊域 Special Fields

Some of the automatically generated fields from  $\S$  4.2.4.2 may be customized. Note that this requires Biber.

```
\DeclareLabelname [\langle entrytype, ... \rangle] \{\langle specification \rangle\}
```

Biber only

Defines the fields to consider when generating the labelname field (see § 4.2.4.2). The \( \specification \) is an ordered list of \field commands. The fields are checked in the order listed and the first field which is available will be used as labelname. This is the default definition:

```
\DeclareLabelname{%
  \field{shortauthor}
  \field{author}
  \field{shorteditor}
  \field{editor}
  \field{translator}
}
```

The labelname field may be customized globally or on a per-type basis. If the optional  $\langle entrytype \rangle$  argument is given, the specification applies to the respective entry type. If

not, it is applied globally. The  $\langle entrytype \rangle$  argument may be a comma-separated list of values. This command may only be used in the preamble.

```
\DeclareLabeldate[\langle entrytype, ... \rangle] \{\langle specification \rangle\}
```

Biber only

Defines the date components to consider when generating labelyear, labelmonth and labelday fields (see § 4.2.4.2). The \( \specification \) is an ordered list of \field or \literal commands. The items are checked in the order listed and the first item which is available will be used to popluate the labelyear, labelmonth and labelday fields. Note that the \field items do not have to be datetype 'date' in the data model so that you can create pseudo-year labels by, for example, using a pubstate field contents, if available, as the year label by defining \DeclareLabeldate suitably. Note also that a \literal command will always be used when found and so this should always be the last thing in the list. If the value of a \literal command is a valid localization string, then this will be resolved in the current language, otherwise the value is used as a literal string as-is. This is the default definition:

```
\DeclareLabeldate{%
  \field{date}
  \field{eventdate}
  \field{origdate}
  \field{urldate}
  \literal{nodate}
}
```

Note that the date field is split by the backend into year, month which are also valid fields in the default data model. In order to support legacy data which directly sets year and/or month, the specification 'date' in \DeclareLabeldate will also match year and month fields, if present. The labelyear, labelmonth and labelday fields may be customized globally or on a per-type basis. If the optional  $\langle entrytype \rangle$  argument is given, the specification applies to the respective entry type. If not, it is applied globally. The  $\langle entrytype \rangle$  argument may be a comma-separated list of values. This command may only be used in the preamble. See also § 4.2.4.3.

```
\DeclareLabeltitle[\langle entrytype, ... \rangle] \{\langle specification \rangle\}
```

Biber only

Defines the fields to consider when generating the labeltitle field (see § 4.2.4.2). The \( \specification \) is an ordered list of \field commands. The fields are checked in the order listed and the first field which is available will be used as labeltitle. This is the default definition:

```
\DeclareLabeltitle{%
  \field{shorttitle}
  \field{title}
}
```

The labeltitle field may be customized globally or on a per-type basis. If the optional  $\langle entrytype \rangle$  argument is given, the specification applies to the respective entry type. If not, it is applied globally. The  $\langle entrytype \rangle$  argument may be a comma-separated list of values. This command may only be used in the preamble.

#### 4.5.10 数据继承 Data Inheritance (crossref)

Biber features a highly customizable cross-referencing mechanism with flexible data inheritance rules. This sections deals with the configuration interface. See appendix B for the default configuration. Note that customized data inheritance requires Biber. It will not work with any other backend. A note on terminology: the *child* or *target* is the entry with the crossref field, the *parent* or *source* is the entry the crossref field points to. The child inherits data from the parent.

```
\DefaultInheritance[\langle exceptions \rangle] { \langle options \rangle}
```

Biber only

Configures the default inheritance behavior. This command may only be used in the preamble. The default behavior may be customized be setting the following *(options)*:

```
all=true, false default: true
```

Whether or not to inherit all fields from the parent by default. all=true means that the child entry inherits all fields from the parent, unless a more specific inheritance rule has been set up with \DeclareDataInheritance. If an inheritance rule is defined for a field, data inheritance is controlled by that rule. all=false means that no data is inherited from the parent by default. Each field to be inherited requires an explicit inheritance rule set up with \DeclareDataInheritance. The package default is all=true.

```
override=true.false default:false
```

Whether or not to overwrite target fields with source fields if both are defined. This applies both to automatic inheritance and to explicit inheritance rules. The package default is override=false, i. e., existing fields of the child entry are not overwritten.

The optional  $\langle exceptions \rangle$  are an undelimited list of \except directives. Spaces, tabs, and line endings may be used freely to visually arrange the  $\langle exceptions \rangle$ . Blank lines are not permissible.

```
\ensuremath{\mbox{except}} \{ \langle source \rangle \} \{ \langle target \rangle \} \{ \langle options \rangle \}
```

Sets the  $\langle options \rangle$  for a specific  $\langle source \rangle$  and  $\langle target \rangle$  combination. The  $\langle source \rangle$  and  $\langle target \rangle$  arguments specify the parent and the child entry type. The asterisk matches all types and is permissible in either argument.

```
\DeclareDataInheritance \{\langle source, ... \rangle\} \{\langle target, ... \rangle\} \{\langle rules \rangle\}
```

Biber only

Declares inheritance rules. The  $\langle source \rangle$  and  $\langle target \rangle$  arguments specify the parent and the child entry type. Either argument may be a single entry type, a comma-separated

list of types, or an asterisk. The asterisk matches all entry types. The  $\langle rules \rangle$  are an undelimited list of \inherit and/or \noinherit directives. Spaces, tabs, and line endings may be used freely to visually arrange the  $\langle rules \rangle$ . Blank lines are not permissible. This command may only be used in the preamble.

```
\inherit[\langle option \rangle] \{\langle source \rangle\} \{\langle target \rangle\}
```

Defines an inheritance rule by mapping a  $\langle source \rangle$  field to a  $\langle target \rangle$  field. The  $\langle option \rangle$  is the override option explained above. When set locally, it takes precedence over any global options set with  $\DefaultInheritance$ .

```
\noinherit{\langle source \rangle}
```

Unconditionally prevents inheritance of the *(source)* field.

#### \ResetDataInheritance

Biber only

Clears all inheritance rules defined with \DeclareDataInheritance. This command may only be used in the preamble.

Here are some practical examples:

```
\DefaultInheritance{all=true, override=false}
```

This example shows how to configure the default inheritance behavior. The above settings are the package defaults.

```
\DefaultInheritance[
  \except{*}{online}{all=false}
]{all=true,override=false}
```

This example is similar to the one above but adds one exception: entries of type @online will, by default, not inherit any data from any parent.

```
\DeclareDataInheritance{collection} {
   \inherit{title} {booktitle}
   \inherit{subtitle} {booksubtitle}
   \inherit{titleaddon} {booktitleaddon}
}
```

So far we have looked at setting up the defaults. For example, all=true means that the publisher field of a source entry is copied to the publisher field of the target entry. In some cases, however, asymmetric mappings are required. They are defined with \DeclareDataInheritance. The above example sets up three typical rules for @incollection entries referencing a @collection. We map the title and related fields of the source to the corresponding booktitle fields of the target.

```
\DeclareDataInheritance{mvbook, book} {inbook, bookinbook} {
  \inherit{author} {author}
  \inherit{author} {bookauthor}
}
```

This rule is an example of one-to-many mapping: it maps the author field of the source to both the author and the bookauthor fields of the target in order to allow for compact inbook/bookinbook entries. The source may be either a @mvbook or a @book entry, the target either an @inbook or a @bookinbook entry.

```
\DeclareDataInheritance{*}{inbook,incollection}{
   \noinherit{introduction}
}
```

This rule prevents inheritance of the introduction field. It applies to all targets of type @inbook or @incollection, regardless of the source entry type.

```
\DeclareDataInheritance{*}{*}{
  \noinherit{abstract}
}
```

This rule, which applies to all entries, regardless of the source and target entry types, prevents inheritance of the abstract field.

```
\DefaultInheritance{all=true, override=false}
\ResetDataInheritance
```

This example demonstrates how to emulate traditional BibTeX's cross-referencing mechanism. It enables inheritance by default, disables overwriting, and clears all other inheritance rules and mappings.

## 4.6 辅助命令

本节的工具用来分析和保存参考文献数据而不是格式化或者打印它们。

## 4.6.1 数据命令

本节的命令允许以 low-level 方式访问未格式化的参考文献数据。这些命令不是用来输出,而是用来将数据保存到临时宏中,可以用于下一步的比较。

```
\thefield{\langle field\rangle}
```

展开为未格式化的〈field〉。如果〈field〉未定义那么展开为一个空字符串。

```
\strfield{\langle field\rangle}
```

类似于\thefield命令,但其值经自动净化,以便安全的用于构成控制序列名。

```
\csfield{\langle field\rangle}
              类似于\thefield命令,但禁止展开
  \usefield{\langle command \rangle} {\langle field \rangle}
             执行(command)命令使用未格式化的(field)作为其参数
   \thelist{\langle list\}
             展开为未格式化的〈literal list〉。如果 list 未定义那么展开为一个空字符串。注意该
              命令中将〈literal list〉转存为本宏包使用的内部格式。这一格式不适合打印。
   \theta \in \{ (name \ list) \}
             展开为未格式化的(name list)。如果 list 未定义那么展开为一个空字符串。注意该
              命令中将(name list)转存为本宏包使用的内部格式。这一格式不适合打印。
 \savefield{\langle field \rangle \} \{\langle macro \rangle \}
\savefield* { \langle field \rangle } { \langle macro \rangle }
             将未格式化的\langle field \rangle拷贝到一个\langle macro \rangle中。不带星的命令全局的定义\langle macro \rangle,而
             带星的命令是局部定义。
  \sim \left( \left\langle literal \ list \right\rangle \right) \left\{ \left\langle macro \right\rangle \right\}
 将未格式化的〈literal list〉拷贝到一个〈macro〉中。不带星的命令全局的定义〈macro〉,
              而带星的命令是局部定义。
  \sin savename {\langle name \ list \rangle} {\langle macro \rangle}
             将未格式化的(name list)拷贝到一个(macro)中。不带星的命令全局的定义(macro),
```

 $\sim savename * {\langle name list \rangle} {\langle macro \rangle}$ 

而带星的命令是局部定义。

 $\sin savefieldcs {\langle field \rangle} {\langle csname \rangle}$  $\sin savefieldcs* {\langle field \rangle} {\langle csname \rangle}$ 

> 类似于\savefield命令,当将控制序列名(csname)(即没有斜杠)作为参数,而不 是宏。

 $\sides$  \savelistcs{\langle list\rangle} {\langle csname\rangle} \savelistcs\*{\langle list\rangle} \( \langle csname \rangle \)

> 类似于\savelist命令,当将控制序列名(csname)(即没有斜杠)作为参数,而不 是宏。

```
\square cs \{ \langle name \ list \rangle \} \{ \langle csname \rangle \}  \square cs * \{ \langle name \ list \rangle \} \{ \langle csname \rangle \}
```

类似于\savename命令,当将控制序列名\(csname\)(即没有斜杠)作为参数,而不是宏。

从之前用\savefield命令定义的 $\langle macro \rangle$ 中将 $\langle field \rangle$ 恢复回来。该域是在局部范围内恢复。

 $\rcstorelist{\langle literal \ list \rangle} {\langle macro \rangle}$ 

从之前用\savelist命令定义的\macro\中将\(literal list\)恢复回来。该 list 是在局部范围内恢复。

 $\rownian { (name list) } { (macro) }$ 

从之前用\savename命令定义的〈macro〉中将〈name list〉恢复回来。该 list 是在局部范围内恢复。

 $\left( \left( field \right) \right)$ 

在局部范围内清除〈field〉。以这种方式清除的域对于后续的数据命令来说相当于 没有定义。

\clearlist{\langle list\rangle}

在局部范围内清除〈literal list〉。以这种方式清除的 list 对于后续的数据命令来说相当于没有定义。

 $\clearname \{ \langle name \ list \rangle \}$ 

在局部范围内清除 $\langle name\ list \rangle$ 。以这种方式清除的 list 对于后续的数据命令来说相当于没有定义。

#### 4.6.2 独立判断命令

本节的命令是不同类型的 stand-alone 判断命令,用于参考文献著录和标注样式中。

 $\left\langle field\right\rangle$  {  $\left\langle field\right\rangle$  } {  $\left\langle false\right\rangle$  }

展开为\(true\),如果\(field\)未定义,否则展开为\(false\)

 $\left\langle iflistundef\left\{ \left\langle literal\ list\right\rangle \right\} \left\{ \left\langle true\right\rangle \right\} \left\{ \left\langle false\right\rangle \right\}$ 

展开为\(\true\), 如果\(\literal list\)未定义, 否则展开为\(\false\)

 $\ightharpoonup$   $\igh$ 

展开为\(true\),如果\(name list\)未定义,否则展开为\(false\)

```
\left\langle field 1 \right\rangle  { \left\langle field 2 \right\rangle } { \left\langle frue \right\rangle } { \left\langle false \right\rangle }
                                                                                                                                                                                      展开为〈true〉,如果〈field 1〉和〈field 2〉相等,否则展开为〈false〉
                           \left\{\left\langle literal\ list\ 1\right\rangle\right\} \left\{\left\langle literal\ list\ 2\right\rangle\right\} \left\{\left\langle true\right\rangle\right\} \left\{\left\langle false\right\rangle\right\}
                                                                                                                                                                                     展开为(true),如果(literal list 1)和(literal list 2)相等,否则展开为(false)
                           \forall i fname sequal \{ \langle name list 1 \rangle \} \{ \langle name list 2 \rangle \} \{ \langle true \rangle \} \{ \langle false \rangle \}
                                                                                                                                                                                     展开为(true),如果(name list 1)和(name list 2)相等,否则展开为(false)
               \left\langle field \right\rangle \left\langle field \right\rangle \left\langle false \left\langle false \right\rangle \left\langle false \right\rangle \left\langle fals
                                                                                                                                                                                     展开为\langle true \rangle,如果\langle field \rangle的值和\langle macro \rangle的定义相等,否则展开为\langle false \rangle。<sup>37</sup>
                           \left\langle iflistequals \left\langle (literal \ list) \right\rangle \left\langle (macro) \right\rangle \left\langle (true) \right\rangle \left\langle (false) \right\rangle
                                                                                                                                                                                      展开为〈true〉,如果〈literal list〉的值和〈macro〉的定义相等,否则展开为〈false〉。
                           \langle name\ list \rangle  { \langle macro \rangle  } { \langle true \rangle  } { \langle false \rangle  }
                                                                                                                                                                                     展开为〈true〉,如果〈name list〉的值和〈macro〉的定义相等,否则展开为〈false〉。
    \left\langle field\right\rangle  { \left\langle csname\right\rangle  } { \left\langle true\right\rangle  } { \left\langle false\right\rangle  }
                                                                                                                                                                                      类似于\iffieldequals,但将控制序列名(csname)(不带斜杠)作为参数,而不
                                                                                                                                                                                      是一个宏名。
              \langle iflistequalcs \{\langle literal \ list \rangle\} \{\langle csname \rangle\} \{\langle true \rangle\} \{\langle false \rangle\}
                                                                                                                                                                                      类似于\iflistequals,但将控制序列名(csname)(不带斜杠)作为参数,而不是
                                                                                                                                                                                      一个宏名。
              \langle ifnameequalcs \{\langle name \ list \rangle\} \{\langle csname \rangle\} \{\langle true \rangle\} \{\langle false \rangle\}
                                                                                                                                                                                      类似于\ifnameequals,但将控制序列名\csname\(不带斜杠)作为参数,而不是
                                                                                                                                                                                     一个宏名。
\left\langle field \right\rangle \left\langle f
                                                                                                                                                                                      展开为〈true〉,如果〈field〉的值和字符串〈string〉的定义相等,否则展开为〈false〉。该
                                                                                                                                                                                      命令是鲁棒的。
                                      \left\{\left\langle field\right\rangle\right\} \left\{\left\langle true\right\rangle\right\} \left\{\left\langle false\right\rangle\right\}
                                                                                                                                                                                      如果一个条目定义了crossref/xref,该命令检测(field)是否与 cross-referenced
```

如果一个条目定义了crossref/xref,该命令检测 $\langle field \rangle$ 是否与 cross-referenced 父条目相关联。如果子条目的 $\langle field \rangle$ 与父条目对应的 $\langle field \rangle$ 相等,那么执行 $\langle true \rangle$ ,否则执行 $\langle false \rangle$ 。如果crossref/xref未定义,总是执行 $\langle false \rangle$ 。该命令是鲁棒的。crossref和 xref域的描述见 § 2.2.3,更多关于 cross-referencing 的信息见 § 2.4.1。

<sup>37</sup>可以用于改进 gb7714-2015 中的新闻和标准的判断

```
\left\langle iflistxref\left\langle (literal\ list)\right\rangle \right\rangle \left\langle (false)\right\rangle
```

类似于\iffieldxref命令,但检测〈literal list〉是否与 cross-referenced 父条目相关联。crossref和 xref域的描述见§ 2.2.3,更多关于 cross-referencing 的信息见§ 2.4.1。

 $\infty$  \iff if name xref { \( name \ list \) } { \( \tau e^{\} \) } { \( \false \) }

类似于\iffieldxref命令,但检测〈name list〉是否与 cross-referenced 父条目相关联。crossref和 xref域的描述见 § 2.2.3,更多关于 cross-referencing 的信息见 § 2.4.1。

 $\ifcurrentfield{\langle field \rangle} {\langle true \rangle} {\langle false \rangle}$ 

执行 $\langle true \rangle$ ,如果当前域为 $\langle field \rangle$ ,否则执行 $\langle false \rangle$ 。该命令是鲁棒的。它主要用于域格式指令中,如果在其它环境中总是执行 $\langle false \rangle$ 。

\ifcurrentlist{\langle list\rangle} \langle \text{\langle list\rangle} \langle \langle true\rangle} \langle \langle \text{\langle false} \rangle\$

执行 $\langle true \rangle$ ,如果当前 list 为 $\langle literal\ list \rangle$ ,否则执行 $\langle false \rangle$ 。该命令是鲁棒的。它主要用于域格式指令中,如果在其它环境中总是执行 $\langle false \rangle$ 。

 $\ightharpoonup$   $\{\langle name\ list \rangle\} \{\langle true \rangle\} \{\langle false \rangle\}$ 

执行 $\langle true \rangle$ ,如果当前 list 为 $\langle name\ list \rangle$ ,否则执行 $\langle false \rangle$ 。该命令是鲁棒的。它主要用于域格式指令中,如果在其它环境中总是执行 $\langle false \rangle$ 。

 $\langle false \rangle$ 

执行 $\langle true \rangle$ ,如果useprefix选项打开(无论是全局的还是针对当前条目),否则执行 $\langle false \rangle$ 。该选项的细节见§3.1.3。

 $\langle false \rangle$ 

这只是下面的\ifuse<name>宏的一个特例,因为author是默认数据模型的一部分所以放到这里来说。执行 $\langle true \rangle$ ,如果useauthor选项打开 (无论是全局的还是针对当前条目),否则执行 $\langle false \rangle$ 。该选项的细节见§3.1.3。

\ifuseeditor $\{\langle true \rangle\}$   $\{\langle false \rangle\}$ 

这只是下面的\ifuse<name>宏的一个特例,因为editor是默认数据模型的一部分所以放到这里来说。执行 $\langle true \rangle$ ,如果useeditor选项打开 (无论是全局的还是针对当前条目),否则执行 $\langle false \rangle$ 。该选项的细节见 § 3.1.3。

 $\forall \text{ifusetranslator} \{\langle true \rangle\} \{\langle false \rangle\}$ 

这只是下面的\ifuse<name>宏的一个特例,因为translator是默认数据模型的一部分所以放到这里来说。执行 $\langle true \rangle$ ,如果usetranslator选项打开 (无论是全局的还是针对当前条目),否则执行 $\langle false \rangle$ 。该选项的细节见§3.1.3。

### $\forall ifuse < name > {\langle true \rangle} {\langle false \rangle}$

展开为〈*true*〉,如果选项use<name>打开(无论全局还是当前条目的选项),否则展开为〈*false*〉。这一选项的细节详见第§3.1.3节。

#### $\left\langle false\right\rangle$

展开为 $\langle true \rangle$ ,如果文献表中只有以labelname为名的一片文献,否则展开为 $\langle false \rangle$ 。如果没有labelname为名的条目,当文献表中有以labeltitle为题的文献则展开为 $\langle true \rangle$ ,否则展开为 $\langle false \rangle$ 。如果条目既没设置labelname也没设置labeltitle,总是展开为 $\langle false \rangle$ 。注意该功能需要显式的打开宏包选项singletitle才行。

## $\left\langle ifandothers \left\langle \left\langle list \right\rangle \right\rangle \left\langle \left\langle true \right\rangle \right\rangle \left\langle \left\langle false \right\rangle \right\rangle$

展开为〈true〉,如果〈list〉已定义并且在bib文件中以关键词'and others'截短了,否则展开为〈false〉。〈list〉可以是 literal 或 name 列表。

#### $\langle false \rangle$

展开为〈true〉,如果当前姓名列表已经截短或将截短,否则展开为〈false〉。该命令用于姓名列表的格式化指令中,在其它地方使用将展开为〈false〉。该命令对当前列表执行与\ifandothers判断一样的操作。如果判断结果为否,它将检测listtotal是否大于liststop。该命令用于格式化命令中用以决定是否需要在列表默认打印"and others" or "et al."这样的标注。注意: 当需要检测实在列表中间或者末尾时,即listcount是否小于或等于liststop,详见第 § 4.4.1节。

## $\langle false \rangle$

类似于\ifmorenames,但检测 literal 列表。用于 literal 列表的格式化指令,其它地方用总是展开为〈false〉。

### $\left\langle false \right\rangle$

根据firstinits包选项的状态,展开为 $\langle true \rangle$ 或 $\langle false \rangle$ (见第§3.1.2.3节)。该命令用于姓名列表的格式化指令。

#### \ifterseinits $\{\langle true \rangle\}$ $\{\langle false \rangle\}$

根据terseinits包选项的状态,展开为 $\langle true \rangle$ 或 $\langle false \rangle$ (见第§3.1.2.3节)。该命令用于姓名列表的格式化指令。

## $\forall fentrytype \{\langle type \rangle\} \{\langle true \rangle\} \{\langle false \rangle\}$

如果当前处理条目类型是〈type〉,则展开为〈true〉,否则展开为〈false〉。

#### 

如果 $\langle keyword \rangle$ 能在当前处理的条目的keywords域中找到,展开为 $\langle true \rangle$ ,否则展开为 $\langle false \rangle$ 。

 $\left(\frac{\langle entry key \rangle}{\langle keyword \rangle} \right) \left(\frac{\langle true \rangle}{\langle false \rangle}\right)$ 

当条目关键词作为\ifkeyword命令参数的变化形式,在判断当前处理条目是否是某一条目时很有用。

 $\langle category \{ \langle category \rangle \} \{ \langle true \rangle \} \{ \langle false \rangle \}$ 

执行〈true〉,如果当前正在处理条目被指派为由\addtocategory命令定义的〈category〉中,否则执行〈false〉。

 $\ightharpoonup \{\langle entrykey \rangle\} \{\langle category \rangle\} \{\langle true \rangle\} \{\langle false \rangle\}$ 

当条目关键词作为\ifcategory命令参数时的变化形式,在判断当前处理条目 是否是某一条目时很有用。

 $\ightharpoonup \fill \$ 

展开为〈true〉,如果当前条目之前已经被引用过,否则展开为〈false〉。该命令是鲁棒的,用于标注样式中。如果文档中有refsection环境,引用追踪是基于这些环境的。注意:引用追踪器需要显式的以包选项citetracker打开,如果追踪器未打开,该命令总是展开为〈false〉。也可以参考第 § 4.6.4节的\citetrackertrue和\citetrackerfalse开关。

 $\left\langle entrykey \right\rangle \left\{ \left\langle true \right\rangle \right\} \left\{ \left\langle false \right\rangle \right\}$ 

当条目关键词作为

\ifciteseen命令参数时的变化形式。因为\(\)entrykey\先于判断展开,它也可以用来测试在xref等域中的条目关键词。

\ifentryseen{\thefield{xref}}{true}{false}

除了一个额外参数,\ifentryseen的操作类似于\ifciteseen。

 $\left\langle entrykey \right\rangle$  {  $\left\langle false \right\rangle$ }

如果 $\langle entrykey \rangle$ 出现当前文献表中,执行 $\langle true \rangle$ ,否则执行 $\langle false \rangle$ 。该命令用于参考文献著录样式。

 $\left\langle false\right\rangle$ 

如果当前处理条目是引用列表中的第一个,执行〈true〉,否则执行〈false〉。该命令依赖于citecount, citetotal, multicitecount 和 multicitetotal计数器 (见§4.10.5),因此只能用于\DeclareCiteCommand命令定义的标注命令的循环执行代码〈loopcode〉中。

 $\left\langle false\right\rangle$ 

类似于\iffirstcitekey,但判断的是是否为引用列表中的最后一个。

### $\left\langle \left\langle true\right\rangle \right\rangle \left\langle \left\langle false\right\rangle \right\rangle$

如果当前处理条目于前一条相同,展开为 $\langle true \rangle$ ,否则展开为 $\langle false \rangle$ 。该命令用于标注样式。如果有refsection环境,追踪器是基于这些环境的。注意:'ibidem'追踪器需要由ibidtracker包选项显式的打开。该判断命令的运行方式与追踪器运行的模式相关,详见§3.1.2.3。如果追踪器未打开,总是展开为 $\langle false \rangle$ 。也可以参考§4.6.4节的 $\langle false \rangle$ 。也可以

#### $\left\langle \text{ifciteidem} \left\langle \text{true} \right\rangle \right\rangle \left\langle \text{false} \right\rangle$

如果当前处理条目的责任者(即作者或编者)于前一条目的相同,展开为 $\langle true \rangle$ ,否则展开为 $\langle false \rangle$ 。该命令用于标注样式。如果有refsection环境,追踪器是基于这些环境的。注意: 'idem' 追踪器需要由idemtracker包选项显式的打开。该判断命令的运行方式与追踪器运行的模式相关,详见§ 3.1.2.3。如果追踪器未打开,总是展开为 $\langle false \rangle$ 。也可以参考§ 4.6.4节的 $\langle tetrackertrue$ 

## $\left\langle false \right\rangle$

该命令类似于\ifciteibid,但只要当前处理等条目的作者或编者与前一条目相同,则展开为 $\langle true \rangle$ 。注意: 'opcit' 追踪器需要由opcittracker包选项显式的打开。该判断命令的运行方式与追踪器运行的模式相关,详见§ 3.1.2.3。如果追踪器未打开,总是展开为 $\langle false \rangle$ 。也可以参考§ 4.6.4节的\citetrackertrue和\citetrackerfalse开关。

# $\left\langle false\right\rangle$

该命令类似于\ifopcit,但还要比较 $\langle postnote \rangle$ 的参数,如果他们相同且是数值 (§ 4.6.2节的\ifnumerals命令判断),则展开为 $\langle true \rangle$ 。即: 如果引文的页码与前一文献相同则展开为 true。注意: 'loccit' 追踪器需要由loccittracker包选项显式的打开。该判断命令的运行方式与追踪器运行的模式相关,详见 § 3.1.2.3。如果追踪器未打开,总是展开为 $\langle false \rangle$ 。也可以参考 § 4.6.4节的\citetrackertrue和\citetrackerfalse开关。

#### $\left\langle false\right\rangle$

该命令的运行与pagetracker包选项相关,如果选项设置成 page,当当前项是页中的第一项,展开为 $\langle true \rangle$ ,否则展开为 $\langle false \rangle$ 。如果选项设置成 spread,当当前项是合页中的第一项,展开为 $\langle true \rangle$ ,否则展开为 $\langle false \rangle$ 。如果选项未打开,总是展开为 $\langle false \rangle$ 。根据所处环境不同,'item'可以是一个标注,或者参考文献表中的条目。注意该命令区分正文文本和脚注,例如,当在某页的第一个脚注中使用,即便是文中有一个标注且先于该脚注。也可以参考§ 4.6.4节的\pagetrackertrue和\pagetrackerfalse开关。

#### $\forall ifsamepage \{ \langle instance 1 \rangle \} \{ \langle instance 2 \rangle \} \{ \langle true \rangle \} \{ \langle false \rangle \}$

如果两个引用实例位于同于页或者同一合页中,展开为〈true〉,否则为〈false〉。一个引用实例可以是一个标注也可以是文献表中的条目。这些实例用instcount计

数区分,见§4.10.5。该命令的运行与pagetracker包选项相关,如果选项设置成 spread,其本质是'if same spread'(是否同意合页) 的判断。如果选项未打开,总是展开为 $\langle false \rangle$ 。参数 $\langle instance 1 \rangle$ 和 $\langle instance 2 \rangle$ 以e-TeX's \numexpr方式当成整数表达式处理。这意味着可以在参数中计算。比如:

\ifsamepage{\value{instcount}}{\value{instcount}-1}{true}{false}

注意:\value命令不是以\the为前缀,在第二个参数中做了减法运算。如果 $\langle instance 1 \rangle$  或  $\langle instance 2 \rangle$ 是无效数字 (比如一个负值),总是展开为 $\langle false \rangle$ 。也要注意该命令不区分正文和脚注。也可以参考 § 4.6.4节的\pagetrackertrue和\pagetrackerfalse开关。

 $\left\langle false \right\rangle$  {  $\left\langle false \right\rangle$  }

如果\string\是一个正整数,展开为\true\,,否则为\false\,,该命令鲁棒。

 $\left\langle false \right\rangle$  {  $\left\langle false \right\rangle$  }

如果\langle 是一个阿拉伯或者罗马数字,展开为\langle true \rangle ,否则为\langle false \rangle ,该命令鲁棒。也可以参考 \rangle 4.6.4节的\Declare NumChars和\NumCheckSetup命令。

 $\langle false \rangle$  {  $\langle false \rangle$  }

如果〈string〉是一个阿拉伯或者罗马数字的范围或列表,展开为〈true〉,否则为〈false〉,该命令鲁棒。相比于\ifnumeral命令,当参数像"52-58","14/15","1,3,5"等时,该命令会执行〈true〉。也可以参考§4.6.4节的\DeclareNumChars,\NumCheckSetup,\DeclareRangeCommands和\NumCheckSetup命令。

 $\langle false \rangle$  {  $\langle true \rangle$  } {  $\langle false \rangle$  }

类似于\ifnumerals,但也考虑§4.6.4节的\DeclarePageCommands命令。

 $\left\langle field\right\rangle$  {  $\left\langle field\right\rangle$  } {  $\left\langle false\right\rangle$  }

类似于\ifinteger命令,但使用 $\langle field \rangle$ 的值而不是一个字符串,如果域未定义,执行 $\langle false \rangle$ 。

 $\left\langle field\right\rangle$  {  $\left\langle field\right\rangle$  } {  $\left\langle false\right\rangle$  }

类似于\ifnumeral命令,但使用 $\langle field \rangle$ 的值而不是一个字符串,如果域未定义,执行 $\langle false \rangle$ 。

 $\left\langle field\right\rangle$  {  $\left\langle field\right\rangle$  } {  $\left\langle false\right\rangle$  }

类似于\ifnumerals命令,但使用 $\langle field \rangle$ 的值而不是一个字符串,如果域未定义,执行 $\langle false \rangle$ 。<sup>38</sup>

-

<sup>38</sup>是否可以用来解析卷期的范围?

```
\left\langle field\right\rangle  { \left\langle field\right\rangle  } { \left\langle false\right\rangle  }
```

类似于\ifpages命令,但使用 $\langle field \rangle$ 的值而不是一个字符串,如果域未定义,执行 $\langle false \rangle$ 。

 $\left\langle \text{ifbibstring} \left\langle \text{string} \right\rangle \right\rangle \left\langle \text{true} \right\rangle \left\langle \text{false} \right\rangle$ 

如果〈string〉是已知的本地化关键词,展开为〈true〉,否则〈false〉。默认定义的本地化字符串见§4.9.2。新的字符串可以用命令\NewBibliographyString定义。

 $\langle string \langle string \rangle \} \langle true \rangle \} \langle false \rangle \}$ 

类似于\ifbibstring,但\string\是展开的。

 $\left\langle \left\langle field\right\rangle \right\rangle \left\langle \left\langle true\right\rangle \right\rangle \left\langle \left\langle false\right\rangle \right\rangle$ 

类似于\ifbibstring,但使用 $\langle field \rangle$ 域的值而不是一个字符串,如果域未定义,执行 $\langle false \rangle$ 。

 $\langle false \rangle$  {  $\langle false \rangle$  }

展开为\(true\)如果\(entrytype\)的驱动存在,否则为\(false\)。

 $\langle false \rangle$ 

如果 Biblatex 的标点追踪器将当前位置的本地化字符串大写,则执行 $\langle true \rangle$ ,否则执行 $\langle false \rangle$ 。给命令在格式化指令中对于姓名的某一部分做有条件的大写处理时有用。

 $\langle true \rangle \} \{ \langle false \rangle \}$ 

当处于标注中则展开为 $\langle true \rangle$ ,否则为 $\langle false \rangle$ 。注意这一命令与其所在的最外层环境有关。比如,当由\DeclareCiteCommand命令定义的标注命令执行一个由\DeclareBibliographyDriver定义的驱动,则任何在该驱动中的\ifcitation都会展开为 $\langle true \rangle$ 。在§4.11.6可以看到一个实例。

 $\left\langle false\right\rangle$ 

当处于文献表中则展开为 $\langle true \rangle$ ,否则为 $\langle false \rangle$ 。注意这一命令与其所在的最外层环境有关。比如,当由\DeclareBibliographyDriver命令定义的驱动执行一个由\DeclareCiteCommand定义的标注,则任何在该标注中的\ifbibliography都会展开为 $\langle true \rangle$ 。在§4.11.6可以看到一个实例。

 $\langle false \rangle$ 

根据§3.1.1的natbib选项展开为〈true〉或〈false〉。

 $\ightharpoonup \langle true \rangle \} \{ \langle false \rangle \}$ 

根据§3.1.2.1的indexing选项展开为〈true〉或〈false〉。

 $\left\langle false \right\rangle$ 

根据 § 3.1.2.1的indexing选项展开为(true)或(false)。

 $\left\langle false \right\rangle$ 

当处于脚注中时,展开为(true), 否则为(false)。注意: 在minipage中的脚注被认 为正文的一部分。当处于页面底部的脚注中或者由endnotes提供的 endnotes 中 时,只会展开为\(true\)。

citecounter 这一计数器表示当前处理条目在当前 reference section 中的引用次数。注意该功能 需要以包选项citecounter显式的打开。如果选项设置为 context,正文和脚 注中的引用分别计数。这种情况下,citecounter记录其所在环境中的值。

uniquename

这一计数器用于labelname列表。它以每个名字为基础进行设置。如果姓不同, 它的值设置为 0, 当增加姓名的其它部分的首字母使得姓名能区分, 则设置为 1,如果需要完整的姓名才能区分,则设置为2。作者年值和作者标题值得标 注格式需要这一信息来增加姓名的其它部分以对姓相同的作者进行引用。比如: 当引用列表中有一个'John Doe' 和一个'Edward Doe', 该计数器将设置为 1。如 果有有一个'John Doe'和一个'John Doe',该计数器将设置为 2。如果选项设置 成 init/allinit/mininit, 那么计数器将限制值最大为 1。这对于标注样 式不打印全名而使用首字母来区分姓名很有用。如果添加首字母还无法区分姓 名, uniquename将设置为 0。该功能需要以包选项uniquename显式的打开。注 意uniquename 是对\printnames局部的,仅根据labelname列表或其来源姓 名列表 (典型如author 或editor) 设置。它的值在任何正文中都是 0, 即它仅在 处理姓名的格式化指令中计算,更多细节和实例见§4.11.4。

uniquelist 该计数器用于labelname列表。它以每个域为基础进行设置。它的值表示当使 用maxnames/minnames自动将姓名列表截短后导致标注歧义时,消除歧义最 小需要的姓名数。比如,有一篇作者是'Doe/Smith/Johnson'的文献和另一篇作 者是'Doe/Edwards/Williams'的文献,设置 maxnames=1 将导致两篇的作者都 是'Doe et al.'。这种情况下,两个条目的labelname列表的uniquelist将设置成 2,因为至少需要两个名字来区分。注意uniquelist是对\printnames命令局部 的,仅根据labelname列表或其来源姓名列表 (典型如author 或editor)设置。 它的值在任何正文中都是 0, 即它仅在处理姓名的格式化指令中计算, 如果该值存 在,则\printnames命令在处理姓名列表时将自动应用,即自动覆盖maxnames/ minnames。该功能需要以包选项uniquelist显式的打开。更多细节和实例见 § 4.11.4°

parenlevel 圆括号和/或方括号的嵌套层级。该信息仅在§3.1.2.3的parentracker选项打开 的情况下提供。

# 4.6.3 使用\ifboolexpr和\ifthenelse的判断

第 § 4.6.2节介绍的判断可以与etoolbox宏包提供的\ifboolexpr命令 和ifthen宏包提供的\ifthenelse命令一同使用。这种情况下,其语法略 有差异,判断命令的\(true\)和\(false\)参数自动省略,而直接传递给\ifboolexpr Biber only

Biber only

或 \ifthenelse。注意,使用这些命令需要一些计算代价。如果不需要一些布尔操作,使用 § 4.6.2节的 stand-alone 判断命令更高效。

```
\ightharpoonup \{\langle expression \rangle\} \{\langle true \rangle\} \{\langle false \rangle\}
              该etoolbox包命令允许进行包括布尔运算和编组的复杂判断。
              \ifboolexpr{ (
                                   test {\ifnameundef{editor}}
                                   and
                                   not test {\iflistundef{location}}
                                or test {\iffieldundef{year}}
                 }
                 { . . . }
                 { . . . }
\forall fthenelse \{ \langle tests \rangle \} \{ \langle true \rangle \} \{ \langle false \rangle \}
              该ifthen包命令允许进行包括布尔运算和编组的复杂判断。
              \ifthenelse{ \(
                                    \ifnameundef{editor}
                                    \and
                                    \not \iflistundef{location}
                                \)
                                \or \iffieldundef{year}
                 }
```

Biblatex 提供的附加判断命令仅在标注命令和文献表中使用\ifboolexpr或\ifthenelse命令时可用。

#### 4.6.4 综合命令

{ . . . }
{ . . . }

本节介绍参考文献著录和标注样式中使用的一些综合命令和小工具。

定义一个用于后面\usebibmacro调用的宏。该命令的语法类似于\newcommand,除了\(\(\name\)\可以包含一些数字或标点,但不以斜杠开头。可选参数\(\arguments\)是一个整数用于指定宏需要处理的参数数量。如果\(\optional\)给出,它指定了该宏的第一个参数的默认值,这第一个参数自动变成为可选参数。相比于\newcommand,当宏已经定义时,\newbibmacro命令会给出一个警告信息,

并自动转换为\renewbibmacro命令。类似于\newcommand,该命令的常规形式在定义中使用\long前缀,而带星的命令则没有。如果一个宏声明为 long,它的参数可以包含\par记号。提供\newbibmacro和\renewbibmacro命令是为了方便使用,样式作者也可以使用\newcommand 或\def。然而,需要注意,共享文件 biblatex.def 中的绝大多数定义都是用\newbibmacro定义的,因此,要使用和修改它们要用相应的方式处理。

```
\label{lem:condition} $$\operatorname{\continuous} {\continuous} {\c
```

类似于\newbibmacro,但用于重定义(name)。相比于\newcommand,当宏未定义时,\renewbibmacro命令给出一个警告信息,并自动转换为\newbibmacro命令。

```
\label{lem:condition} $$ \operatorname{coptional} {\langle name \rangle} [\langle arguments \rangle] [\langle optional \rangle] {\langle definition \rangle} $$ \operatorname{coptional} {\langle definition \rangle} $$
```

类似于\newbibmacro,但仅在(name)未定义时定义宏。该命令概念上类似于\providecommand。

```
\usebibmacro\{\langle name \rangle\}
\usebibmacro*\{\langle name \rangle\}
```

该命令执行由\newbibmacro定义的宏〈name〉。如果宏带参数,只要简单的跟在〈name〉后面即可。该命令的常规形式会处理〈name〉,而带星的命令不会。

这两个命令用来保存和恢复〈command〉,其中〈command〉必须是以斜杠开头的命令。两个命令都在局部范围内起作用。它们主要用于本地化文件中。

这两个命令用来保存和恢复宏 $\langle name \rangle$ ,其中 $\langle name \rangle$ 由 $\backslash newbibmacro$ 定义的宏的标识。两个命令都在局部范围内起作用。它们主要用于本地化文件中。

```
\label{eq:controller} $$\operatorname{centry type} : {\langle format \rangle} $$\operatorname{centry type} : {\langle format \rangle} $$
```

这 两 个 命 令 用 来 保 存 和 恢 复 格 式 化 指 令 $\langle format \rangle$ , 其 中 $\langle format \rangle$ 由\DeclareFieldFormat定义。两个命令都在局部范围内起作 用。它们主要用于本地化文件中。

```
\label{eq:continuous} $$\operatorname{savelistformat}[\langle entry\ type\rangle] \{\langle format\rangle\} $$\operatorname{continuous}(\langle entry\ type\rangle) \} \{\langle format\rangle\} $$
```

这两个命令用来保存和恢复格式化指令 $\langle format \rangle$ ,其中 $\langle format \rangle$ 由\DeclareListFormat定义。两个命令都在局部范围内起作用。它们主要用于本地化文件中。

```
\space{1mm} \spa
```

这两个命令用来保存和恢复格式化指令 $\langle format \rangle$ ,其中 $\langle format \rangle$ 由\DeclareNameFormat定义。两个命令都在局部范围内起作用。它们主要用于本地化文件中。

如果参考文献宏(name)未定义,展开为(true)否则为(false)。

如果参考文献格式化指令(format)未定义,展开为(true)否则为(false)。otherwise.

```
\usedriver{\langle code \rangle} {\langle entrytype \rangle}
```

执行〈entrytype〉类条目的参考文献驱动。在由\DeclareCiteCommand定义的标注命令的〈loopcode〉中调用该命令是打印类似于一个参考文献条目的完整标注的简单方法。诸如\newblock等命令无法用于标注,自动省略。附加的初始化命令可以通过〈code〉参数传递。该参数在一个编组内执行,这一编组用于运行相应驱动。注意:该参数语法上是必须的,但可以留空。也要注意该命令会自动切换语言,如果autolang包选项打开的话。

```
\bibhypertarget\{\langle name \rangle\}\{\langle text \rangle\}
```

A wrapper for hyperref's \hypertarget command. The  $\langle name \rangle$  is the name of the anchor, the  $\langle text \rangle$  is arbitrary printable text or code which serves as an anchor. If there are any refsection environments in the document, the  $\langle name \rangle$  is local to the current environment. If the hyperref package option is disabled or the hyperref package has not been loaded, this command will simply pass on its  $\langle text \rangle$  argument. See also the formatting directive bibhypertarget in § 4.10.4.

```
\left\langle \left\langle name\right\rangle \right\rangle \left\langle \left\langle text\right\rangle \right\rangle
```

A wrapper for hyperref's \hyperlink command. The  $\langle name \rangle$  is the name of an anchor defined with \bibhypertarget, the  $\langle text \rangle$  is arbitrary printable text or code to be transformed into a link. If there are any refsection environments in the document, the  $\langle name \rangle$  is local to the current environment. If the hyperref package option is disabled or the hyperref package has not been loaded, this command will

simply pass on its  $\langle text \rangle$  argument. See also the formatting directive bibhyperlink in § 4.10.4.

```
\bibhyperref[\langle entrykey\rangle] \{ \langle text\rangle \}
```

Transforms  $\langle text \rangle$  into an internal link pointing to  $\langle entrykey \rangle$  in the bibliography. If  $\langle entrykey \rangle$  is omitted, this command uses the key of the entry currently being processed. This command is employed to transform citations into clickable links pointing to the corresponding entry in the bibliography. The link target is marked automatically by Biblatex. If there are multiple bibliographies in a document, the target will be the first occurence of  $\langle entrykey \rangle$  in one of the bibliographies. If there are refsection environments, the links are local to the environment. See also the formatting directive biblyperref in § 4.10.4.

```
\left\langle false \right\rangle
```

Expands to  $\langle true \rangle$  if the hyperref package option is enabled (which implies that the hyperref package has been loaded), and to  $\langle false \rangle$  otherwise.

```
\docsvfield{\langle field \rangle}
```

Similar to the \docsvlist command from the etoolbox package, except that it takes a field name as its argument. The value of this field is parsed as a comma-separated list. If the  $\langle field \rangle$  is undefined, this command expands to an empty string.

```
\forcsvfield{\landler\}}{\landler\}}{\landler\}
```

Similar to the \forcsvlist command from the etoolbox package, except that it takes a field name as its argument. The value of this field is parsed as a commaseparated list. If the  $\langle field \rangle$  is undefined, this command expands to an empty string.

```
MakeCapital\{\langle text \rangle\}
```

Similar to \MakeUppercase but only coverts the first printable character in  $\langle text \rangle$  to uppercase. Note that the restrictions that apply to \MakeUppercase also apply to this command. Namely, all commands in  $\langle text \rangle$  must either be robust or prefixed with \protect since the  $\langle text \rangle$  is expanded during capitalization. Apart from Ascii characters and the standard accent commands, this command also handles the active characters of the inputenc package as well as the shorthands of the babel package. If the  $\langle text \rangle$  starts with a control sequence, nothing is capitalized. This command is robust.

```
\MakeSentenceCase { \langle text \rangle } \MakeSentenceCase* { \langle text \rangle }
```

Converts its  $\langle text \rangle$  argument to sentence case, i. e., the first word is capitalized and the remainder of the string is converted to lowercase. This command is robust. The starred variant differs from the regular version in that it considers the language of the entry, as

specified in the langid field. It only converts the  $\langle text \rangle$  to sentence case if the langid field is undefined or if it holds a language declared with \DeclareCaseLangs (see below). Otherwise, the  $\langle text \rangle$  is not altered in any way. It is recommended to use \MakeSentenceCase\* rather than the regular variant in formatting directives. Both variants support the traditional BibTeX convention for bib files that anything wrapped in a pair of curly braces is not modified when changing the case. For example:

```
\MakeSentenceCase{an Introduction to LaTeX}
\MakeSentenceCase{an Introduction to {LaTeX}}
```

#### would yield:

```
An introduction to latex
An introduction to LaTeX
```

In bib files designed with traditional BibTeX in mind, it has been fairly common to only wrap single letters in braces to prevent case-changing:

```
title = {An Introduction to {L}a{T}e{X}}
```

The problem with this convention is that the braces will suppress the kerning on both sides of the enclosed letter. It is preferable to wrap the entire word in braces as shown in the first example.

```
\mbox{\t mkpageprefix}[\langle pagination \rangle][\langle postpro \rangle]\{\langle text \rangle\}
```

This command is intended for use in field formatting directives which format the page numbers in the  $\langle postnote \rangle$  argument of citation commands and the pages field of bibliography entries. It will parse its  $\langle text \rangle$  argument and prefix it with 'p.' or 'pp.' by default. The optional  $\langle pagination \rangle$  argument holds the name of a field indicating the pagination type. This may be either pagination or bookpagination, with pagination being the default. The spacing between the prefix and the  $\langle text \rangle$  may be modified by redefining \ppspace. The default is an unbreakable interword space. See §§ 2.3.10 and 3.12.3 for further details. See also \DeclareNumChars, \DeclareRangeChars, \DeclareRangeCommands, and \NumCheckSetup. The optional  $\langle postpro \rangle$  argument specifies a macro to be used for post-processing the  $\langle text \rangle$ . If only one optional argument is given, it is taken as  $\langle pagination \rangle$ . Here are two typical examples:

```
\DeclareFieldFormat{postnote} {\mkpageprefix[pagination] { #1} }
\DeclareFieldFormat{pages} {\mkpageprefix[bookpagination] { #1} }
```

The optional argument pagination in the first example is omissible.

<sup>&</sup>lt;sup>39</sup>By default, converting to sentence case is enabled for the following language identifiers: american, british, canadian, english, australian, newzealand as well as the aliases USenglish and UKenglish. Use \DeclareCaseLangs to extend or change this list.

Input	Output		
	mincomprange=10	mincomprange=100	mincomprange=1000
11-15	11-5	11–15	11-15
111-115	111-5	111-5	111-115
1111-1115	1111-5	1111-5	1111-5
	maxcomprange=1000	maxcomprange=100	maxcomprange=10
1111-1115	1111-5	1111-5	1111-5
1111-1155	1111-55	1111-55	1111-1155
1111-1555	1111-555	1111-1555	1111-1555
	mincompwidth=1	mincompwidth=10	mincompwidth=100
1111-1115	1111-5	1111-15	1111-115
1111-1155	1111-55	1111-55	1111-155
1111-1555	1111-555	1111-555	1111-555

Table 10: \mkcomprange setup

```
\mbox{\t mkpagetotal } [\langle pagination \rangle] [\langle postpro \rangle] {\langle text \rangle}
```

This command is similar to \mkpageprefix except that it is intended for the pagetotal field of bibliography entries, i.e., it will print "123 pages" rather than "page 123". The optional  $\langle pagination \rangle$  argument defaults to bookpagination. The spacing inserted between the pagination suffix and the  $\langle text \rangle$  may be modified by redefining the macro \mathbb{npspace}. The optional  $\langle postpro \rangle$  argument specifies a macro to be used for post-processing the  $\langle text \rangle$ . If only one optional argument is given, it is taken as  $\langle pagination \rangle$ . Here is a typical example:

```
\DeclareFieldFormat{pagetotal}{\mkpagetotal[bookpagination]{#1}}
```

The optional argument bookpagination is omissible in this case.

```
\mkcomprange [\langle postpro \rangle] {\langle text \rangle} \mkcomprange* [\langle postpro \rangle] {\langle text \rangle}
```

This command, which is intended for use in field formatting directives, will parse its  $\langle text \rangle$  argument for page ranges and compress them. For example, "125–129" may be formatted as "125–9". You may configure the behavior of \mkcomprange by adjusting the LaTeX counters mincomprange, maxcomprange, and mincompwidth, as illustrated in table 10. The default settings are 10, 100000, and 1, respectively. This means that the command tries to compress as much as possible by default. Use \setcounter to adjust the parameters. The scanner recognizes \bibrangedash and hyphens as range dashes. It will normalize the dash by replacing any number of consecutive hyphens with \bibrangedash. Lists of ranges delimited with \bibrangessep (Biber<sup>40</sup>) or commas/semicolons (BibTeX) are also supported. With Biber, the scanner will normalise any comma or semi-colons surrounded by optional

<sup>&</sup>lt;sup>40</sup>Biber will always convert commas/semicolon multi-range separators into \bibrangessep so that it can be controlled in the style.

space by replacing them with \bibrangessep. If you want to hide a character from the list/range scanner for some reason, wrap the character or the entire string in curly braces. The optional  $\langle postpro \rangle$  argument specifies a macro to be used for post-processing the  $\langle text \rangle$ . This is important if you want to combine \mkcomprange with other formatting macros which also need to parse their  $\langle text \rangle$  argument, such as \mkpageprefix. Simply nesting these commands will not work as expected. Use the  $\langle postpro \rangle$  argument to set up the processing chain as follows:

```
\DeclareFieldFormat{postnote}{\mkcomprange[{\mkpageprefix[pagination]}]{#1}}
```

Note that \mkcomprange is executed first, using \mkpageprefix as post-processor. Also note that the  $\langle postpro \rangle$  argument is wrapped in an additional pair of braces. This is only required in this particular case to prevent LaTeX's optional argument scanner from getting confused by the nested brackets. The starred version of this command differs from the regular one in the way the  $\langle postpro \rangle$  argument is applied to a list of values. For example:

```
\mkcomprange[\mkpageprefix]{5, 123-129, 423-439}
\mkcomprange*[\mkpageprefix]{5, 123-129, 423-439}

will output:

pp. 5, 123-9, 423-39

p. 5, pp. 123-9, pp. 423-39

\mkfirstpage[\langle postpro \rangle ] {\langle text \rangle }

\mkfirstpage*[\langle postpro \rangle ] {\langle text \rangle }
```

This command, which is intended for use in field formatting directives, will parse its  $\langle text \rangle$  argument for page ranges and print the start page of the range only. The scanner recognizes \bibrangedash and hyphens as range dashes. Lists of ranges delimited with \bibrangessep (Biber<sup>41</sup>) or commas/semicolons (BibTeX) are also supported. If you want to hide a character from the list/range scanner for some reason, wrap the character or the entire string in curly braces. The optional  $\langle postpro \rangle$  argument specifies a macro to be used for post-processing the  $\langle text \rangle$ . See \mkcomprange on how to use this argument. The starred version of this command differs from the regular one in the way the  $\langle postpro \rangle$  argument is applied to a list of values. For example:

```
\mkfirstpage[\mkpageprefix]{5, 123-129, 423-439}
\mkfirstpage*[\mkpageprefix]{5, 123-129, 423-439}
```

# will output:

```
pp. 5, 123, 423
p. 5, p. 123, p. 423
```

<sup>&</sup>lt;sup>41</sup>Biber will always convert commas/semicolon multi-range separators into \bibrangessep so that it can be controlled in the style.

This command will parse its argument as a range and return the length of the range. It will return -1 for open-ended ranges.

```
\rangelen{5-10} returns '5'
\rangelen{-10} returns '0'
\rangelen{5-} returns '0'
\rangelen{5} returns '1'
```

This can be used as part of tests in styles which require, for example, 'f' as a suffix for ranges of only two pages as when a page range '36-37' should be printed as '36f'. This could be done using \intnumcomp:

```
\ifnumcomp{\rangelen{\thefield{pages}}}{=}{1}{add 'f'}{do nothing}
```

# $\frac{\langle range field \rangle}$

Biber only

Takes the name of a bibfield declared as a range field in the data model and returns the length of the range. This is calculated by Biber, can handle many special cases and is generally more robust than \rangelen. It will return -1 for open ended ranges. Specifically \frangelen can:

- •Calculate the total of multiple ranges in the same field such as '1-10, 20-30'
- •Handle implicit ranges such as '22-4' and '130-33'
- •Handle roman numeral ranges in upper and lower case and consisting of both ASCII and Unicode roman numeral representations.

Here are some examples:

```
pages = '10'
                             \frangelen{pages} returns '1'
pages = '10-15'
                             \frangelen{pages} returns '6'
pages = '10-15,47-53'
                             \frangelen {pages} returns '13'
pages = '10-'
                             \frangelen { pages } returns '-1'
pages = '-10'
                             \frangelen{pages} returns '-1'
pages = '48-9'
                             \frangelen{pages} returns '2'
pages = '172-77'
                             \frangelen{pages} returns '6'
pages = 'i-vi'
                             \frangelen{pages} returns '6'
pages = 'X-XX'
                             \frangelen {pages} returns '11'
pages = 'VII-xii'
                             \frangelen{pages} returns '6'
                            \frangelen {pages} returns '14'
pages = 'VII-xii, 145-7, 135-39'
```

As with \rangelen, \frangelen can be used in tests:

```
\ifnumcomp{\frangelen{pages}}{=}{1}{add 'f'}{do nothing}
```

```
\DeclareNumChars \{\langle characters \rangle\} \DeclareNumChars* \{\langle characters \rangle\}
```

This command configures the \ifnumeral, \ifnumerals, and \ifpages tests from § 4.6.2. The setup will also affect \iffieldnum, \iffieldnums, \iffieldpages as well as \mkpageprefix and \mkpagetotal. The  $\langle characters \rangle$  argument is an undelimited list of characters which are to be considered as being part of a number. The regular version of this command replaces the current setting, the starred version appends its argument to the current list. The default setting is:

```
\DeclareNumChars{.}
```

This means that a (section or other) number like '3.4.5' will be considered as a number. Note that Arabic and Roman numerals are detected by default, there is no need to declare them explicitly.

This command configures the \ifnumerals and \ifpages tests from § 4.6.2. The setup will also affect \iffieldnums and \iffieldpages as well as \mkpageprefix and \mkpagetotal. The  $\langle characters \rangle$  argument is an undelimited list of characters which are to be considered as range indicators. The regular version of this command replaces the current setting, the starred version appends its argument to the current list. The default setting is:

```
\DeclareRangeChars { ~,; -+/}
```

This means that strings like '3–5', '35+', '8/9' and so on will be considered as a range by \ifnumerals and \ifpages. Non-range characters in such strings are recognized as numbers. So strings like '3a–5a' and '35b+' are not deemed to be ranges by default. See also §§ 2.3.10 and 3.12.3 for further details.

This command is similar to  $\parbox{DeclareRangeChars}$ , except that the  $\langle commands \rangle$  argument is an undelimited list of commands which are to be considered as range indicators. The regular version of this command replaces the current setting, the starred version appends its argument to the current list. The default list is rather long and should cover all common cases; here is a shorter example:

\DeclareRangeCommands{\&\bibrangedash\textendash\textemdash\psq\psqq}

See also §§ 2.3.10 and 3.12.3 for further details.

228

This command is similar to \DeclareRangeCommands, except that it only affects the \ifpages and \iffieldpages tests but not \ifnumerals and \iffieldnums. The default setting is:

```
\DeclarePageCommands{\pno\ppno}
```

```
\Model NumCheckSetup \{ \langle code \rangle \}
```

Use this command to temporarily redefine any commands which interfere with the tests performed by \ifnumeral, \ifnumerals, and \ifpages from § 4.6.2. The setup will also affect \iffieldnum, \iffieldnums, \iffieldnums, \iffieldpages as well as \mkpageprefix and \mkpagetotal. The  $\langle code \rangle$  will be executed in a group by these commands. Since the above mentioned commands will expand the string to be analyzed, it is possible to remove commands to be ignored by the tests by making them expand to an empty string. See also §§ 2.3.10 and 3.12.3 for further details.

```
\DeclareCaseLangs \{\langle languages \rangle\} \DeclareCaseLangs \{\langle languages \rangle\}
```

Defines the list of languages which are considered by the \MakeSentenceCase\* command as it converts a string to sentence case. The \(\languages\rangle\) argument is a commaseparated list of babel/polyglossia languages identifiers. The regular version of this command replaces the current setting, the starred version appends its argument to the current list. The default setting is:

```
\DeclareCaseLangs{%
  american, british, canadian, english, australian, newzealand,
  USenglish, UKenglish}
```

See the babel/polyglossia manuals and table 2 for a list of languages identifiers.

```
\BibliographyWarning { \langle message \rangle }
```

This command is similar to  $\parking but prints the entry key of the entry currently being processed in addition to the input line number. It may be used in the bibliography as well as in citation commands. If the <math>\mbox{\it message}\$  is fairly long, use  $\mbox{\it MessageBreak}$  to include line breaks. Note that the standard  $\parking \mbox{\it End}\$  command does not provide a meaningful clue when used in the bibliography since the input line number is the line on which the  $\parking \mbox{\it End}\$  command was given.

229

#### $\RequireBiber[\langle severity \rangle]$

This command is intended for use in cbx/bbx files and in the @preamble of bib files. It checks the selected backend and warns if it is not Biber. The optional \( \severity \) argument is an integer specifying the severity. The value 1 triggers an informational message stating that Biber is recommended; 2 triggers a warning stating that Biber is required and the style/bib file may not work properly; 3 triggers an error stating that Biber is strictly required and the style/bib file will not work at all with any other backend. If \RequireBiber is used multiple times, the highest \( \severity \) takes precedence. cbx/bbx files on the one hand and the @preamble snippets of all bib files on the other are tracked separately. If the optional \( \severity \) argument is omitted, the default severity is 2 (warning).

\pagetrackertru@These commands activate or deactivate the citation tracker locally (this will affect the \pagetrackerfal %@ffirstonpage and \ifsamepage test from § 4.6.2). They are intended for use in the definition of citation commands or anywhere in the document body. If a citation command is to be excluded from page tracking, use \pagetrackerfalse in the \langle precode \rangle argument of \DeclareCiteCommand. See § 4.3.1 for details. Note that these commands have no effect if page tracking has been disabled globally.

\citetrackertru@These commands activate or deactivate all citation trackers locally (this will affect the \citetrackerfal \@fciteseen, \ifentryseen, \ifciteibid, and \ifciteidem tests from \§ 4.6.2). They are intended for use in the definition of citation commands or anywhere in the document body. If a citation command is to be excluded from tracking, use \citetrackerfalse in the \( \precode \) argument of \DeclareCiteCommand. See \§ 4.3.1 for details. Note that these commands have no effect if tracking has been disabled globally.

\backtrackertru@These commands activate or deactivate the backref tracker locally. They are intended \backtrackerfal for use in the definition of citation commands or anywhere in the document body. If a citation command is to be excluded from backtracking, use \backtrackerfalse in the \langle precode \rangle argument of \DeclareCiteCommand. Note that these commands have no effect if the backref option has been not been set globally.

# 4.7 标点和间距

The Biblatex package provides elaborate facilities designed to manage and track punctuation and spacing in the bibliography and in citations. These facilities work on two levels. The high-level commands discussed in § 4.7.1 deal with punctuation and white-space inserted by the bibliography style between the individual segments of a bibliography entry. The commands in §§ 4.7.2, 4.7.3, 4.7.4 work at a lower level. They use TeX's space factor and modified space factor codes to track punctuation in a robust and efficient way. This way it is possible to detect trailing punctuation marks within fields, not only those explicitly inserted between fields. The same technique is also used for automatic capitalization of localization strings, see \DeclareCapitalPunctuation

in § 4.7.5 as well as § 4.8 for details. Note that these facilities are only made available locally in citations and bibliographies. They will not affect any other part of a document.

#### 4.7.1 块和单元标点 Block and Unit Punctuation

The major segments of a bibliography entry are 'blocks' and 'units'. A block is the larger segment of the two, a unit is shorter or at most equal in length. For example, the values of fields such as title or note usually form a unit which is separated from subsequent data by a period or a comma. A block may comprise several fields which are treated as separate units, for example publisher, location, and year. The segmentation of an entry into blocks and units is at the discretion of the bibliography style. An entry is segmented by inserting \newblock and \newunit commands at suitable places and \finentry at the very end (see § 4.2.3 for an example). See also § 4.11.7 for some practical hints.

Newblock Records the end of a block. This command does not print anything, it merely marks the end of the block. The block delimiter \newblockpunct will be inserted by a subsequent \printtext, \printfield, \printlist, \printnames, or \bibstring command. You may use \newblock at suitable places without having to worry about spurious blocks. A new block will only be started by the next \printfield (or similar) command if this command prints anything. See § 4.11.7 for further details.

\newunit Records the end of a unit and puts the default delimiter \newunitpunct in the punctuation buffer. This command does not print anything, it merely marks the end of the unit. The punctuation buffer will be inserted by the next \printtext, \printfield, \printlist, \printnames, or \bibstring command. You may use \newunit after commands like \printfield without having to worry about spurious punctuation and whitespace. The buffer will only be inserted by the next \printfield or similar command if both fields are non-empty. This also applies to \printtext, \printlist, \printnames, and \bibstring. See § 4.11.7 for further details.

\finentry Inserts \finentrypunct. This command should be used at the very end of every bibliography entry.

```
\setunit{\(\rho\)punctuation\)}
\setunit*{\(\rho\)punctuation\)}
```

The \setunit command is similar to \newunit except that it uses \( \lambda punctuation \rangle \) instead of \newunitpunct. The starred variant differs from the regular version in that it checks if the last \printtext, \printfield, \printlist, \printnames, or \bibstring command did actually print anything. If not, it does nothing.

```
\printunit{\langle punctuation\rangle}
\printunit*{\langle punctuation\rangle}
```

The \printunit command is similar to \setunit except that \( \printtien \) persists in the buffer until the next \printtext, \printfield, \printlist, \printnames, or \bibstring command.

```
\strut {\langle command \rangle}
```

This command, which is intended for use in field formatting directives, provides an alternative way of dealing with unit punctuation after a field printed in a different font (for example, a title printed in italics). The standard LaTeX way of dealing with this is adding a small amount of space, the so-called italic correction. This command allows adapting the punctuation to the font of the preceding field. The  $\langle command \rangle$  should be a text font command which takes one argument, such as  $\langle emph \ or \ textbf$ . This command will only affect punctuation marks inserted by one of the commands from § 4.7.3. The font adaption is applied to the next punctuation mark only and will be reset automatically thereafter. If you want to reset it manually before it takes effect, issue  $\langle emph \ em$ 

\resetpunctfont This command resets the unit punctuation font defined with \setpunctfont before it takes effect. If the punctfont package option is disabled, this command does nothing.

# 4.7.2 标点判断 Punctuation Tests

The following commands may be used to test for preceding punctuation marks at any point in citations and the bibliography.

```
\left\langle false \right\rangle
```

Executes  $\langle true \rangle$  if preceded by any punctuation mark except for an abbreviation dot, and  $\langle false \rangle$  otherwise.

```
\left\langle true \right\rangle  { \left\langle false \right\rangle  }
```

Executes  $\langle true \rangle$  if preceded by a terminal punctuation mark, and  $\langle false \rangle$  otherwise. A terminal punctuation mark is any punctuation mark which has been registered for automatic capitalization, either with \DeclareCapitalPunctuation or by default, see § 4.7.5 for details. By default, this applies to periods, exclamation marks, and question marks.

 $\left\langle character \right\rangle \left\langle character$ 

Executes  $\langle true \rangle$  if preceded by the punctuation mark  $\langle character \rangle$ , and  $\langle false \rangle$  otherwise. The  $\langle character \rangle$  may be a comma, a semicolon, a colon, a period, an exclamation mark, a question mark, or an asterisk. Note that a period denotes an end-of-sentence period. Use the asterisk to test for the dot after an abbreviation. If this command is used in a formatting directive for name lists, i. e., in the argument to \DeclareNameFormat, the  $\langle character \rangle$  may also be an apostrophe.

## 4.7.3 添加标点 Adding Punctuation

下面的命令设计用来重复标点。参考文献和标注样式总需要使用这些命令来代替原样输出标点符号。本节中所有的\add...命令自动利用\unspace命令移除前面的空白(见§ 4.7.4)。注意:下面讨论的所有的\add...命令的作用是宏包默认的,无论 Biblatex 换哪种语言都会重新恢复。其作用可以通过\DeclarePunctuationPairs命令进行调整,见§ 4.7.5。节

\addot 如果前面输出的不是任何一种标点符号,那么添加一个句点 (period)。该命令的目的是在一个缩写后面插入点 (dot)。以这种方式插入的点被认为与其它标点命令插入的标点性质相同。该命令也用来将前面如实输出的句点 (原样输出的句点, literal period) 转换成一个缩写的点。

\addcomma 如果前面输出不是一个逗号 (comma)、分号 (semicolon)、冒号 (colon) 和句点 (period),那么添加一个逗号。

\addsemicolon Adds a semicolon unless it is preceded by a comma, another semicolon, a colon, or a period.

\addcolon Adds a colon unless it is preceded by a comma, a semicolon, another colon, or a period.

\addperiod 如果前面输出不是一个缩写点或其他任何标点符号,那么添加一个句号。该命令 也可以用来将前面插入的缩写点转换为句号,比如在句子的末尾<sup>42</sup>。

\addexclam Adds an exclamation mark unless it is preceded by any punctuation mark except for an abbreviation dot.

\addquestion Adds a question mark unless it is preceded by any punctuation mark except for an abbreviation dot.

\isdot 当前面输出的是句号的时候,将其转换为缩写的点,如果前面是其它符号那么不 添加任何符号。

\nopunct Adds an internal marker which will cause the next punctuation command to print nothing.

<sup>42</sup>不是很理解,前面如果是缩写的点,那么不加入句号,那么缩写的点就转变为句号了?

#### 4.7.4 添加空格 Adding Whitespace

The following commands are designed to prevent spurious whitespace. Bibliography and citation styles should always use these commands instead of literal whitespace. In contrast to the commands in §§ 4.7.2 and 4.7.3, they are not restricted to citations and the bibliography but available globally.

\unspace

Removes preceding whitespace, i. e., removes all skips and penalties from the end of the current horizontal list. This command is implicitly executed by all of the following commands.

\addspace Adds a breakable interword space.

\addnbspace Adds a non-breakable interword space.

\addthinspace Adds a breakable thin space.

\addnbthinspace Adds a non-breakable thin space. This is similar to \, and \thinspace.

\addlowpenspace Adds a space penalized by the value of the lownamepenalty counter, see §§ 3.9.3 and 4.10.3 for details.

\addhighpenspace Adds a space penalized by the value of the highnamepenalty counter, see §§ 3.9.3 and 4.10.3 for details.

\addlpthinspace Similar to \addlowpenspace but adds a breakable thin space.

\addhpthinspace Similar to \addhighpenspace but adds a breakable thin space.

\addabbrvspace Adds a space penalized by the value of the abbrvpenalty counter, see §§ 3.9.3 and 4.10.3 for details.

\addabthinspace Similar to \addabbrvspace but using a thin space.

\adddotspace Executes \adddot and adds a space penalized by the value of the abbrvpenalty counter, see §§ 3.9.3 and 4.10.3 for details.

\addslash Adds a breakable slash. This command differs from the \slash command in the LaTeX kernel in that a linebreak after the slash is not penalized at all.

> Note that the commands in this section implicitly execute \unspace to remove spurious whitespace, hence they may be used to override each other. For example, you may use \addnbspace to transform a previously inserted interword space into a non-breakable one and \addspace to turn a non-breakable space into a breakable one

43

<sup>&</sup>lt;sup>43</sup>注意有的时候\unspace看似能够起到作用,但其实并不能随意使用的。在 beamer 中 printtext 老是有些问题, 可能是实现 printtext 命令的依赖命令,在 beamer 中重定义了,跟 aritcle 文档类中的情况差别很大。

#### 4.7.5 标点设置和大写 Configuring Punctuation and Capitalization

The following commands configure various features related to punctuation and automatic capitalization.  $^{44}$ 

#### \DeclareAutoPunctuation{\langle characters\rangle}

This command defines the punctuation marks to be considered by the citation commands as they scan ahead for punctuation. Note that  $\langle characters \rangle$  is an undelimited list of characters. Valid  $\langle characters \rangle$  are period, comma, semicolon, colon, exclamation and question mark. The default setting is:

```
\DeclareAutoPunctuation{.,;:!?}
```

This definition is restored automatically whenever the autopunct package option is set to true. Executing \DeclareAutoPunctuation{} is equivalent to setting autopunct=false, i. e., it disables this feature.

```
\DeclareCapitalPunctuation{\langle characters\rangle}
```

When Biblatex inserts localization strings, i. e., key terms such as 'edition' or 'volume', it automatically capitalizes them after terminal punctuation marks. This command defines the punctuation marks which will cause localization strings to be capitalized if one of them precedes a string. Note that  $\langle characters \rangle$  is an undelimited list of characters. Valid  $\langle characters \rangle$  are period, comma, semicolon, colon, exclamation and question mark. The package default is:

```
\DeclareCapitalPunctuation{.!?}
```

Using \DeclareCapitalPunctuation with an empty argument is equivalent to disabling automatic capitalization. Since this feature is language specific, this command must be used in the argument to \DefineBibliographyExtras (when used in the preamble) or \DeclareBibliographyExtras (when used in a localization module). See §§ 3.8 and 4.9 for details. By default, strings are capitalized after periods, exclamation marks, and question marks. All strings are generally capitalized at the beginning of a paragraph (in fact whenever TeX is in vertical mode).

```
\DeclarePunctuationPairs { \( \text{identifier} \) } \{ \( \characters \) \\}
```

Use this command to declare valid pairs of punctuation marks. This will affect the punctuation commands discussed in § 4.7.3. For example, the description of \addcomma states that this command adds a comma unless it is preceded by another comma, a semicolon, a colon, or a period. In other words, commas after abbreviation dots, exclamation marks, and question marks are permitted. These valid pairs are declared as follows:

```
\DeclarePunctuationPairs{comma}{*!?}
```

<sup>44</sup>这里的 capitalization 是大写的意思么?

The (identifier) selects the command to be configured. The identifiers correspond to the names of the punctuation commands from § 4.7.3 without the \add prefix, i.e., valid (identifier) strings are dot, comma, semicolon, colon, period, exclam, question. The *(characters)* argument is an undelimited list of punctuation marks. Valid (characters) are comma, semicolon, colon, period, exclamation mark, question mark, and asterisk. A period in the *(characters)* argument denotes an end-of-sentence period, an asterisk the dot after an abbreviation. This is the default setup, which is automatically restored whenever Biblatex switches languages and corresponds to the behavior described in § 4.7.3:

```
\DeclarePunctuationPairs{dot}{}
\DeclarePunctuationPairs{comma}{*!?}
\DeclarePunctuationPairs{semicolon}{*!?}
\DeclarePunctuationPairs{colon} { *!?}
\DeclarePunctuationPairs{period}{}
\DeclarePunctuationPairs{exclam} { * }
\DeclarePunctuationPairs{question} { * }
```

Since this feature is language specific, \DeclarePunctuationPairs must be used in the argument to \DefineBibliographyExtras (when used in the preamble) or \DeclareBibliographyExtras (when used in a localization module). See §§ 3.8 and 4.9 for details. Note that some localization modules may use a setup which is different from the package default. 45

```
\DeclareQuotePunctuation { \( \characters \) \)}
```

This command controls 'American-style' punctuation. The \mkbibquote wrapper from § 4.10.4 can interact with the punctuation facilities discussed in §§ 4.7.1, 4.7.3, 4.7.4. Punctuation marks after \mkbibquote will be moved inside the quotes if they have been registered with \DeclareQuotePunctuation. Note that \( \characters \) is an undelimited list of characters. Valid (characters) are period, comma, semicolon, colon, exclamation and question mark. Here is an example:

```
\DeclareQuotePunctuation{.,}
```

Executing \DeclareQuotePunctuation{} is equivalent to disabling this feature. This is the package default. Since this feature is language specific, this command must be used in the argument to \DefineBibliographyExtras (when used in the preamble) or \DeclareBibliographyExtras (when used in a localization module). See §§ 3.8 and 4.9 for details. See also § 3.10.1.

\uspunctuation A shorthand using the lower-level commands \DeclareQuotePunctuation and \DeclarePunctuationPairs to activate 'American-style' punctuation. See § 3.10.1 for details. This shorthand is provided for convenience only. The effective settings are applied by the lower-level commands.

<sup>&</sup>lt;sup>45</sup>As of this writing, the american module uses different settings for 'American-style' punctuation.

\stdpunctuation Undoes the settings applied by \uspunctuation, restoring standard punctuation.

As standard punctuation is the default setting, you only need this command to override a previously executed \uspunctuation command. See § 3.10.1 for details.

#### 4.7.6 修正标点追踪 Correcting Punctuation Tracking

The facilities for punctuation tracking and automatic capitalization are very reliable under normal circumstances, but there are always marginal cases which may require manual intervention. Typical cases are localization strings printed as the first word in a footnote (which is usually treated as the beginning of a paragraph as far as capitalization is concerned, but TeX is not in vertical mode at this point) or punctuation after periods which are not really end-of-sentence periods (for example, after an ellipsis like "[...]" a command such as \addperiod would do nothing since parentheses and brackets are transparent to the punctuation tracker). In such cases, use the following commands in bibliography and citation styles to mark the beginning or middle of a sentence if and where required:

\bibsentence

This command marks the beginning of a sentence. A localization string immediately after this command will be capitalized and the punctuation tracker is reset, i. e., this command hides all preceding punctuation marks from the punctuation tracker and enforces capitalization.

\midsentence

This command marks the middle of a sentence. A localization string immediately after this command will not be capitalized and the punctuation tracker is reset, i. e., this command hides all preceding punctuation marks from the punctuation tracker and suppresses capitalization.

\midsentence\*

The starred variant of \midsentence differs from the regular one in that a preceding abbreviation dot is not hidden from the punctuation tracker, i.e., any code after \midsentence\* will see a preceding abbreviation dot. All other punctuation marks are hidden from the punctuation tracker and capitalization is suppressed.

# 4.8 本地化字符串 Localization Strings

Localization strings are key terms such as 'edition' or 'volume' which are automatically translated by Biblatex's localization modules. See § 4.9 for an overview and § 4.9.2 for a list of all strings supported by default. The commands in this section are used to print the localized term.

\bibstring[ $\langle wrapper \rangle$ ] { $\langle key \rangle$ }

Prints the localization string  $\langle key \rangle$ , where  $\langle key \rangle$  is an identifier in lowercase letters (see § 4.9.2). The string will be capitalized as required, see § 4.7.5 for details. Depending on the abbreviate package option from § 3.1.2.1, \bibstring prints the short or the long version of the string. If localization strings are nested, i. e., if \bibstring is used in another string, it will behave like \bibxstring. If the  $\langle wrapper \rangle$  argument

is given, the string is passed to the  $\langle wrapper \rangle$  for formatting. This is intended for font commands such as  $\backslash emph$ .

```
\biblstring[\langle wrapper \rangle] {\langle key \rangle}
                     Similar to \bibstring but always prints the long string, ignoring the abbreviate
                      option.
   \bibsstring[\langle wrapper \rangle] {\langle key \rangle}
                     Similar to \bibstring but always prints the short string, ignoring the abbreviate
                      option.
 \bibcpstring[\langle wrapper \rangle] {\langle key \rangle}
                     Similar to \bibstring but the term is always capitalized.
\bibcplstring[\langle wrapper \rangle] {\langle key \rangle}
                     Similar to \biblstring but the term is always capitalized.
\bibcpsstring[\langle wrapper \rangle] {\langle key \rangle}
                      Similar to \bibsstring but the term is always capitalized.
 \bibucstring[\langle wrapper \rangle] {\langle key \rangle}
                     Similar to \bibstring but the whole term is uppercased.
\bibuclstring[\langle wrapper \rangle] {\langle key \rangle}
                     Similar to \biblstring but the whole term is uppercased.
\bibucsstring[\langle wrapper \rangle] {\langle key \rangle}
                     Similar to \bibsstring but the whole term is uppercased.
 \biblcstring[\langle wrapper \rangle] {\langle key \rangle}
                     Similar to \bibstring but the whole term is lowercased.
\biblclstring[\langle wrapper \rangle] {\langle key \rangle}
                     Similar to \biblstring but the whole term is lowercased.
\biblcsstring[\langle wrapper \rangle] {\langle key \rangle}
                     Similar to \bibsstring but the whole term is lowercased.
   \bibxstring\{\langle key \rangle\}
```

A simplified but expandable version of \bibstring. Note that this variant does not capitalize automatically, nor does it hook into the punctuation tracker. It is intended for special cases in which strings are nested or an expanded localization string is required in a test.

```
\bibxlstring[\langle wrapper \rangle] {\langle key \rangle}
```

Similar to \bibxstring but always uses the long string, ignoring the abbreviate option.

```
\bibxsstring[\langle wrapper \rangle] {\langle key \rangle}
```

Similar to \bibxstring but always uses the short string, ignoring the abbreviate option.

#### \mainlang

Switches from the current language to the main document language. This can be used the  $\langle wrapper \rangle$  argument in the localization string commands above.

# 4.9 本地化模块 Localization Modules

A localization module provides translations for key terms such as 'edition' or 'volume' as well as definitions for language specific features such as the date format and ordinals. These definitions are provided in files with the suffix lbx. The base name of the file must be a language name known to the babel/polyglossia packages. The lbx files may also be used to map babel/polyglossia language names to the backend modules of the Biblatex package. All localization modules are loaded on demand in the document body. Note that the contents of the file are processed in a group and that the category code of the character @ is temporarily set to 'letter'.

# 4.9.1 本地化命令 Localization Commands

The user-level versions of the localization commands were already introduced in § 3.8. When used in lbx files, however, the syntax of localization commands is different from the user syntax in the preamble and the configuration file. When used in localization files, there is no need to specify the  $\langle language \rangle$  because the mapping of strings to a language is already provided by the name of the lbx file.

```
\DeclareBibliographyStrings { \( definitions \) \)}
```

This command is only available in 1bx files. It is used to define localization strings. The  $\langle definitions \rangle$  consist of  $\langle key \rangle = \langle value \rangle$  pairs which assign an expression to an identifier. A complete list of all keys supported by default is given is § 4.9.2. Note that the syntax of the value is different in 1bx files. The value assigned to a key consists of two expressions, each of which is wrapped in an additional pair of brackets. This is best shown by example:

```
\DeclareBibliographyStrings{%
bibliography = {{Bibliography}{Bibliography}},
shorthands = {{List of Abbreviations}{Abbreviations}},
editor = {{editor}{ed.}},
```

```
editors = {{editors}{eds.}},
```

The first value is the long, written out expression, the second one is an abbreviated or short form. Both strings must always be given even though they may be identical if an expression is always (or never) abbreviated. Depending on the setting of the abbreviate package option (see § 3.1.2.1), Biblatex selects one expression when loading the lbx file. There is also a special key named inherit which copies the strings from a different language. This is intended for languages which only differ in a few expressions, such as German and Austrian or American and British English. For example, here are the complete definitions for Austrian:

```
\DeclareBibliographyStrings{%
  inherit = {german},
  january = {{J\"anner}{J\"an.}},
}
```

The above examples are slightly simplified. Real localization files should use the punctuation and formatting commands discussed in §§ 4.7.3 and 3.9 instead of literal punctuation. Here is an excerpt from a real localization file:

```
bibliography = {{Bibliography}{Bibliography}},
shorthands = {{List of Abbreviations}{Abbreviations}},
editor = {{editor}{ed\addot}},
editors = {{editors}{eds\addot}},
byeditor = {{edited by}{ed\addotspace by}},
mathesis = {{Master's thesis}{MA\addabbrvspace thesis}},
```

Note the handling of abbreviation dots, the spacing in abbreviated expressions, and the capitalization in the example above. All expressions should be capitalized as they usually are when used in the middle of a sentence. The Biblatex package will automatically capitalize the first word when required at the beginning of a sentence, see \DeclareCapitalPunctuation in § 4.7.5 for details. Expressions intended for use in headings are special. They should be capitalized in a way that is suitable for titling and should not be abbreviated (but they may have a short form).

```
\InheritBibliographyStrings{\language\}}
```

This command is only available in 1bx files. It copies the localization strings for  $\langle language \rangle$  to the current language, as specified by the name of the 1bx file.

```
\DeclareBibliographyExtras{\langle code \rangle}
```

This command is only available in 1bx files. It is used to adapt language specific features such as the date format and ordinals. The  $\langle code \rangle$ , which may be arbitrary LaTeX code, will usually consist of redefinitions of the formatting commands from § 4.10.2.

```
\UndeclareBibliographyExtras\{\langle code \rangle\}
```

This command is only available in lbx files. It is used to restore any formatting commands modified with \DeclareBibliographyExtras. If a redefined command is included in § 4.10.2, there is no need to restore its previous definition since these commands are localized by all language modules anyway.

```
\InheritBibliographyExtras{\language\}
```

This command is only available in 1bx files. It copies the bibliography extras for  $\langle language \rangle$  to the current language, as specified by the name of the 1bx file.

```
\DeclareHyphenationExceptions { \langle text \rangle }
```

This command corresponds to \DefineHyphenationExceptions from § 3.8. The difference is that it is only available in lbx files and that the  $\langle language \rangle$  argument is omitted. The hyphenation exceptions will affect the language of the lbx file currently being processed.

```
\DeclareRedundantLanguages \{ \langle language, language, ... \rangle \} \{ \langle langid, langid, ... \rangle \}
```

This command provides the language mappings required by the clearlang option from § 3.1.2.1. The  $\langle language \rangle$  is the string given in the language field (without the optional lang prefix);  $\langle langid \rangle$  is babel/polyglossia's language identifier, as given in the optional argument of \usepackage when loading babel or the argument of \setdefaultlanguage or \setdefaultlanguages when using polyglossia. This command may be used in lbx files or in the document preamble. Here are some examples:

Note that this feature needs to be enabled globally with the clearlang option from § 3.1.2.1. If it is disabled, all mappings will be ignored. If the  $\langle langid \rangle$  parameter is blank, Biblatex will clear the mappings for the corresponding  $\langle language \rangle$ , i. e., the feature will be disabled for this  $\langle language \rangle$  only.

```
\DeclareLanguageMapping { \langle language \rangle \} { \langle file \rangle }
```

This command maps a babel/polyglossia language identifier to an lbx file. The  $\langle language \rangle$  must be a language name known to the babel/polyglossia package, i. e., one of the identifiers listed in table 2. The  $\langle file \rangle$  argument is the name of an alternative lbx file without the .lbx suffix. Declaring the same mapping more than once is possible. Subsequent declarations will simply overwrite any previous ones. This command may only be used in the preamble. See § 4.11.8 for further details.

#### $\NewBibliographyString{\langle key \rangle}$

This command, which may be used in the preamble (including cbx and bbx files) as well as in lbx files, declares new localization strings, i.e., it initializes a new  $\langle key \rangle$  to be used in the  $\langle definitions \rangle$  of \DefineBibliographyStrings or \DeclareBibliographyStrings. The  $\langle key \rangle$  argument may also be a commaseparated list of key names. When used in an lbx, the  $\langle key \rangle$  is initialized only for the language specified by the name of the lbx file. The keys listed in § 4.9.2 are defined by default.

#### 4.9.2 本地化关键词 Localization Keys

The localization keys in this section are defined by default and covered by the localization files which come with Biblatex. Note that these strings are only available in citations, the bibliography and bibliography lists. All expressions should be capitalized as they usually are when used in the middle of a sentence. Biblatex will capitalize them automatically at the beginning of a sentence. The only exceptions to these rules are the three strings intended for use in headings.

**4.9.2.1 Headings** The following strings are special because they are intended for use in headings and made available globally via macros. For this reason, they should be capitalized for use in headings and they must not include any local commands which are part of Biblatex's author interface.

bibliography The term 'bibliography', also available as \bibname.

references The term 'references', also available as \refname.

shorthands The term 'list of shorthands' or 'list of abbreviations', also available as \biblistname.

**4.9.2.2 Roles, Expressed as Functions** The following keys refer to roles which are expressed as a function ('editor', 'translator') rather than as an action ('edited by', 'translated by').

editor The term 'editor', referring to the main editor. This is the most generic editorial role.

editors The plural form of editor.

compiler The term 'compiler', referring to an editor whose task is to compile a work.

compilers The plural form of compiler.

founder The term 'founder', referring to a founding editor.

founders The plural form of founder.

continuator An expression like 'continuator', 'continuation', or 'continued', referring to a past editor who continued the work of the founding editor but was subsequently replaced by the current editor.

The plural form of continuator. continuators The term 'redactor', referring to a secondary editor. redactor The plural form of redactor. redactors The term 'reviser', referring to a secondary editor. reviser The plural form of reviser. revisers A term like 'collaborator', 'collaboration', 'cooperator', or 'cooperation', referring to a collaborator secondary editor. The plural form of collaborator. collaborators The term 'translator'. translator translators The plural form of translator. The term 'commentator', referring to the author of a commentary to a work. commentator commentators The plural form of commentators. The term 'annotator', referring to the author of annotations to a work. annotator The plural form of annotators. annotators 4.9.2.3 Concatenated Editor Roles, Expressed as Functions The following keys are similar in function to editor, translator, etc. They are used to indicate additional roles of the editor, e.g., 'editor and translator', 'editor and foreword'. Used if editor/translator are identical. editortr The plural form of editortr. editorstr Used if editor/commentator are identical. editorco The plural form of editorco. editorsco Used if editor/annotator are identical. editoran editorsan The plural form of editoran. editorin Used if editor/introduction are identical. The plural form of editorin. editorsin editorfo Used if editor/foreword are identical. The plural form of editorfo. editorsfo Used if editor/aftword are identical. editoraf editorsaf The plural form of editoraf. Keys for editor/translator/ $\langle role \rangle$  combinations: editortroo Used if editor/translator/commentator are identical. The plural form of editortrco. editorstrco

editortran Used if editor/translator/annotator are identical.

The plural form of editortran. editorstran Used if editor/translator/introduction are identical. editortrin The plural form of editortrin. editorstrin Used if editor/translator/foreword are identical. editortrfo editorstrfo The plural form of editortrfo. editortraf Used if editor/translator/aftword are identical. editorstraf The plural form of editortraf. Keys for editor/commentator/ $\langle role \rangle$  combinations: Used if editor/commentator/introduction are identical. editorcoin editorscoin The plural form of editorcoin. editorcofo Used if editor/commentator/foreword are identical. editorscofo The plural form of editorcofo. Used if editor/commentator/aftword are identical. editorcoaf editorscoaf The plural form of editorcoaf. Keys for editor/annotator/ $\langle role \rangle$  combinations: Used if editor/annotator/introduction are identical. editoranin editorsanin The plural form of editoranin. Used if editor/annotator/foreword are identical. editoranfo The plural form of editoranfo. editorsanfo Used if editor/annotator/aftword are identical. editoranaf The plural form of editoranaf. editorsanaf Keys for editor/translator/commentator/ $\langle role \rangle$  combinations: Used if editor/translator/commentator/introduction are identical. editortrcoin editorstrcoin The plural form of editortrcoin. Used if editor/translator/commentator/foreword are identical. editortrcofo The plural form of editortrcofo. editorstrcofo editortrcoaf Used if editor/translator/commentator/aftword are identical. The plural form of editortrcoaf. editorstrcoaf Keys for editor/annotator/commentator/ $\langle role \rangle$  combinations: Used if editor/annotator/commentator/introduction are identical. editortranin

editorstranin

The plural form of editortranin.

Used if editor/annotator/commentator/foreword are identical. The plural form of editortranfo. editorstranfo Used if editor/annotator/commentator/aftword are identical. editortranaf The plural form of editortranaf. editorstranaf 4.9.2.4 Concatenated Translator Roles, Expressed as Functions The following keys are similar in function to translator. They are used to indicate additional roles of the translator, e.g., 'translator and commentator', 'translator and introduction'. translatorco Used if translator/commentator are identical. translatorsco The plural form of translatorco. Used if translator/annotator are identical. translatoran translatorsan The plural form of translatoran. Used if translator/introduction are identical. translatorin translatorsin The plural form of translatorin. translatorfo Used if translator/foreword are identical. translators fo The plural form of translator fo. translatoraf Used if translator/aftword are identical. translatorsaf The plural form of translatoraf. Keys for translator/commentator/ $\langle role \rangle$  combinations: translatorcoin Used if translator/commentator/introduction are identical. translatorscoin The plural form of translatorcoin. translatorcofo Used if translator/commentator/foreword are identical. translatorscofo The plural form of translatorcofo. translatorcoaf Used if translator/commentator/aftword are identical. translatorscoaf The plural form of translatorcoaf. Keys for translator/annotator/ $\langle role \rangle$  combinations: translatoranin Used if translator/annotator/introduction are identical. The plural form of translatoranin. translatorsanin Used if translator/annotator/foreword are identical. translatoranfo The plural form of translatoranfo. translatorsanfo translatoranaf Used if translator/annotator/aftword are identical.

translatorsanaf The plural form of translatoranaf.

expressed as an action ('edited by', 'translated by') rather than as a function ('editor', 'translator'). The expression '[created] by  $\langle name \rangle$ '. byauthor The expression 'edited by  $\langle name \rangle$ '. byeditor bycompiler The expression 'compiled by  $\langle name \rangle$ '. The expression 'founded by  $\langle name \rangle$ '. byfounder The expression 'continued by  $\langle name \rangle$ '. bycontinuator The expression 'redacted by  $\langle name \rangle$ '. byredactor byreviser The expression 'revised by  $\langle name \rangle$ '. The expression 'reviewed by  $\langle name \rangle$ '. byreviewer An expression like 'in collaboration with  $\langle name \rangle$ ' or 'in cooperation with  $\langle name \rangle$ '. bycollaborator The expression 'translated by  $\langle name \rangle$ ' or 'translated from  $\langle language \rangle$  by  $\langle name \rangle$ '. bytranslator The expression 'commented by  $\langle name \rangle$ '. bycommentator The expression 'annotated by  $\langle name \rangle$ '. byannotator 4.9.2.6 Concatenated Editor Roles, Expressed as Actions The following keys are similar in function to byeditor, bytranslator, etc. They are used to indicate additional roles of the editor, e.g., 'edited and translated by', 'edited and furnished with an introduction by', 'edited, with a foreword, by'. byeditortr Used if editor/translator are identical. byeditorco Used if editor/commentator are identical. byeditoran Used if editor/annotator are identical. Used if editor/introduction are identical. byeditorin Used if editor/foreword are identical. byeditorfo byeditoraf Used if editor/aftword are identical. 4.9.2.5 Roles, Expressed as Actions The following keys refer to roles which are

byeditorcoin Used if editor/commentator/introduction are identical.

Keys for editor/commentator/ $\langle role \rangle$  combinations:

byeditortraf Used if editor/translator/aftword are identical.

byeditorcofo Used if editor/commentator/foreword are identical.

byeditorcoaf Used if editor/commentator/aftword are identical.

Keys for editor/annotator/ $\langle role \rangle$  combinations:

byeditoranin Used if editor/annotator/introduction are identical.

byeditoranfo Used if editor/annotator/foreword are identical.

byeditoranaf Used if editor/annotator/aftword are identical.

Keys for editor/translator/commentator/ $\langle role \rangle$  combinations:

byeditortrcoin Used if editor/translator/commentator/introduction are identical.

byeditortrcofo Used if editor/translator/commentator/foreword are identical.

byeditortrcoaf Used if editor/translator/commentator/aftword are identical.

Keys for editor/translator/annotator/ $\langle role \rangle$  combinations:

byeditortranin Used if editor/annotator/commentator/introduction are identical.

byeditortranfo Used if editor/annotator/commentator/foreword are identical.

byeditortranaf Used if editor/annotator/commentator/aftword are identical.

**4.9.2.7 Concatenated Translator Roles, Expressed as Actions** The following keys are similar in function to bytranslator. They are used to indicate additional roles of the translator, e.g., 'translated and commented by', 'translated and furnished with an introduction by', 'translated, with a foreword, by'.

bytranslatorco Used if translator/commentator are identical.

bytranslatoran Used if translator/annotator are identical.

bytranslatorin Used if translator/introduction are identical.

bytranslatorfo Used if translator/foreword are identical.

bytranslatoraf Used if translator/aftword are identical.

Keys for translator/commentator/ $\langle role \rangle$  combinations:

bytranslatorcoin Used if translator/commentator/introduction are identical.

bytranslatorcofo Used if translator/commentator/foreword are identical.

bytranslatorcoaf Used if translator/commentator/aftword are identical.

Keys for translator/annotator/ $\langle role \rangle$  combinations:

bytranslatoranin Used if translator/annotator/introduction are identical.

bytranslatoranfo Used if translator/annotator/foreword are identical.

bytranslatoranaf Used if translator/annotator/aftword are identical.

tions ('commentator') or as actions ('commented by'). The expression 'with a commentary by  $\langle name \rangle$ '. withcommentator The expression 'with annotations by  $\langle name \rangle$ '. withannotator withintroduction The expression 'with an introduction by  $\langle name \rangle$ '. The expression 'with a foreword by  $\langle name \rangle$ '. withforeword withafterword The expression 'with an afterword by  $\langle name \rangle$ '. 4.9.2.9 Supplementary Material commentary The term 'commentary'. The term 'annotations'. annotations The term 'introduction'. introduction The term 'foreword'. foreword The term 'afterword'. afterword 4.9.2.10 Publication Details The term 'volume', referring to a book. volume The plural form of volume. volumes The term 'in', as used in expressions like 'in \( number of volumes \) volumes'. involumes The term 'volume', referring to a journal. jourvol The term 'series', referring to a journal. jourser The term 'book', referring to a document division. book The term 'part', referring to a part of a book or a periodical. part issue The term 'issue', referring to a periodical. The expression 'new series', referring to a journal. newseries The expression 'old series', referring to a journal. oldseries The term 'edition'. edition The term 'in', referring to the title of a work published as part of another one, e.g., ' $\langle title\ of\ article \rangle$  in  $\langle title\ of\ journal \rangle$ '. The term 'in', as used in expressions like 'volume  $\langle number \rangle$  in  $\langle name\ of\ series \rangle$ '. inseries The term 'of', as used in expressions like 'volume  $\langle number \rangle$  of  $\langle name\ of\ series \rangle$ '. ofseries The term 'number', referring to an issue of a journal. number The term 'chapter', referring to a chapter in a book. chapter The term 'version', referring to a revision number. version

**4.9.2.8 Roles, Expressed as Objects** Roles which are related to supplementary material may also be expressed as objects ('with a commentary by') rather than as func-

```
The term 'reprint'.
        reprint
                 The expression 'reprint of \langle title \rangle'.
      reprintof
                 The expression 'reprinted as \( \title \)'.
      reprintas
                 The expression 'reprinted from \( \text{title} \)'.

                 4.9.2.11 Publication State
                 The expression 'in preparation' (the manuscript is being prepared for publication).
 inpreparation
                 The expression 'submitted' (the manuscript has been submitted to a journal or
     submitted
                 conference).
                 The expression 'forthcoming' (the manuscript has been accepted by a press or
   forthcoming
                 journal).
                 The expression 'in press' (the manuscript is fully copyedited and out of the author's
       inpress
                 hands; it is in the final stages of the production process).
                 The expression 'pre-published' (the manuscript is published in a preliminary form or
  prepublished
                 location, such as online version in advance of print publication).
                 4.9.2.12 Pagination
                The term 'page'.
          page
                 The plural form of page.
         pages
                 The term 'column', referring to a column on a page.
       column
                 The plural form of column.
      columns
                 The term 'section', referring to a document division (usually abbreviated as §).
       section
                 The plural form of section (usually abbreviated as §§).
       sections
                 The term 'paragraph' (i. e., a block of text, not to be confused with section).
     paragraph
                 The plural form of paragraph.
    paragraphs
                 The term 'verse' as used when referring to a work which is cited by verse numbers.
         verse
                 The plural form of verse.
        verses
                 The term 'line' as used when referring to a work which is cited by line numbers.
           line
                 The plural form of line.
          lines
```

```
@report, @misc, and other entries:
            An expression equivalent to the term 'Master's thesis'.
            The term 'PhD thesis', 'PhD dissertation', 'doctoral thesis', etc.
 phdthesis
            An expression equivalent to the term 'Candidate thesis'. Used for 'Candidate' degrees
candthesis
            that have no clear equivalent to the Master's or doctoral level.
techreport
            The term 'technical report'.
            The term 'research report'.
 resreport
            The term 'computer software'.
  software
            The term 'data CD' or 'CD-ROM'.
   datacd
            The term 'audio CD'.
  audiocd
            4.9.2.14 Miscellaneous
            The term to use in place of a date when there is no date for an entry e.g., 'n.d.'
   nodate
            The term 'and', as used in a list of authors or editors, for example.
      and
            The expression 'and others' or 'et alii', used to mark the truncation of a name list.
andothers
 andmore
            Like andothers but used to mark the truncation of a literal list.
            4.9.2.15 Labels The following strings are intended for use as labels, e.g., 'Address:
            \langle url \rangle' or 'Abstract: \langle abstract \rangle'.
            The term 'address' in the sense of an internet address.
            An expression like 'available from \langle url \rangle' or 'available at \langle url \rangle'.
   urlfrom
            An expression like 'accessed on \langle date \rangle', 'retrieved on \langle date \rangle', 'visited on \langle date \rangle',
   urlseen
            referring to the access date of an online resource.
            The term 'file'.
       file
            The term 'library'.
   library
            The term 'abstract'.
  abstract
            The term 'annotations'.
annotation
            4.9.2.16 Citations Traditional scholarly expressions used in citations:
            The term equivalent to the Latin 'idem' ('the same [person]').
            The feminine singular form of idem.
   idemsf
            The masculine singular form of idem.
  idemsm
            The neuter singular form of idem.
   idemsn
            The feminine plural form of idem.
   idempf
```

**4.9.2.13** Types The following keys are typically used in the type field of @thesis,

```
The neuter plural form of idem.
     idempn
              The plural form of idem suitable for a mixed gender list of names.
     idempp
              The term equivalent to the Latin 'ibidem' ('in the same place').
     ibidem
              The term equivalent to the Latin term 'opere citato' ('[in] the work [already] cited').
       opcit
              The term equivalent to the Latin term 'loco citato' ('[at] the place [already] cited').
       loccit
              The term equivalent to the Latin 'confer' ('compare').
      confer
              The term equivalent to the Latin 'sequens' ('[and] the following [page]'), as used to
    sequens
              indicate a range of two pages when only the starting page is provided (e.g., '25 sq.' or
              '25 f.' instead of '25-26').
              The term equivalent to the Latin 'sequentes' ('[and] the following [pages]'), as used to
  sequentes
              indicate an open-ended range of pages when only the starting page is provided (e.g.,
              '25 sqq.' or '25 ff.').
             The term equivalent to the Latin 'passim' ('throughout', 'here and there', 'scatteredly').
     passim
              Other expressions frequently used in citations:
             The term 'see'.
         see
              The expression 'see also'.
     seealso
             An expression like 'see note \( \frac{footnote}{\} \) or 'as in \( \frac{footnote}{\} \)', used to refer to a previous
     seenote
              footnote in a citation.
             An expression like 'see page \langle page \rangle' or 'cited on page \langle page \rangle', used to introduce back
backrefpage
              references in the bibliography.
              The plural form of backrefpage, e.g., 'see pages (pages)' or 'cited on pages
backrefpages
              \langle pages \rangle'.
   quotedin An expression like 'quoted in \( \citation \)', used when quoting a passage which was
              already a quotation in the cited work.
             An expression like 'henceforth cited as (shorthand)', used to introduce a shorthand in
     citedas
              a citation.
             The expression used in some verbose citation styles to differentiate between the page
     thiscite
              range of the cited item (typically an article in a journal, collection, or conference
              proceedings) and the page number the citation refers to. For example: "Author, Title,
              in: Book, pp. 45-61, thiscite p. 52."
              4.9.2.17 Month Names
             The name 'January'.
    january
             The name 'February'.
    february
              The name 'March'.
      march
```

The masculine plural form of idem.

```
The name 'April'.
         april
                The name 'May'.
         may
               The name 'June'.
         june
               The name 'July'.
          july
               The name 'August'.
       august
               The name 'September'.
    september
               The name 'October'.
       october
                The name 'November'.
     november
     december
               The name 'December'.
                4.9.2.18 Language Names
               The language 'American' or 'American English'.
 langamerican
  langbrazilian
               The language 'Brazilian' or 'Brazilian Portuguese'.
   langcatalan
               The language 'Catalan'.
  langcroatian
               The language 'Croatian'.
               The language 'Czech'.
    langczech
               The language 'Danish'.
   langdanish
               The language 'Dutch'.
    langdutch
               The language 'English'.
   langenglish
   langfinnish
               The language 'Finnish'.
    langfrench
               The language 'French'.
               The language 'German'.
   langgerman
               The language 'Greek'.
    langgreek
    langitalian
               The language 'Italian'.
     langlatin
               The language 'Latin'.
               The language 'Norwegian'.
langnorwegian
               The language 'Polish'.
    langpolish
               The language 'Portuguese'.
langportuguese
               The language 'Russian'.
   langrussian
                The language 'Slovene'.
   langslovene
               The language 'Spanish'.
   langspanish
               The language 'Swedish'.
  langswedish
                The following strings are intended for use in phrases like 'translated from [the] English
                by \(\langle translator\rangle \):
```

```
The expression 'from [the] American' or 'from [the] American English'.
                The expression 'from [the] Brazilian' or 'from [the] Brazilian Portuguese'.
  frombrazilian
                The expression 'from [the] Catalan'.
   fromcatalan
                The expression 'from [the] Czech'.
     fromczech
                The expression 'from [the] Croatian'.
  fromcroatian
                The expression 'from [the] Danish'.
    fromdanish
                The expression 'from [the] Dutch'.
    fromdutch
                The expression 'from [the] English'.
   fromenglish
   fromfinnish
                The expression 'from [the] Finnish'.
                The expression 'from [the] French'.
    fromfrench
                The expression 'from [the] German'.
   fromgerman
                The expression 'from [the] Greek'.
     fromgreek
                The expression 'from [the] Italian'.
    fromitalian
                The expression 'from [the] Latin'.
     fromlatin
fromnorwegian
                The expression 'from [the] Norwegian'.
                The expression 'from [the] Polish'.
    frompolish
fromportuguese
                The expression 'from [the] Portuguese'.
                The expression 'from [the] Russian'.
   fromrussian
                The expression 'from [the] Slovene'.
   fromslovene
   fromspanish
                The expression 'from [the] Spanish'.
                The expression 'from [the] Swedish'.
  fromswedish
```

**4.9.2.19 Country Names** Country names are localized by using the string country plus the ISO-3166 country code as the key. The short version of the translation should be the ISO-3166 country code. Note that only a small number of country names is defined by default, mainly to illustrate this scheme. These keys are used in the location list of @patent entries but they may be useful for other purposes as well.

```
countryde The name 'Germany', abbreviated as DE.

countryeu The name 'European Union', abbreviated as EU.

countryep Similar to countryeu but abbreviated as EP. This is intended for patent entries.

countryfr The name 'France', abbreviated as FR.

countryuk The name 'United Kingdom', abbreviated (according to Iso-3166) as GB.

countryus The name 'United States of America', abbreviated as US.
```

**4.9.2.20 Patents and Patent Requests** Strings related to patents are localized by using the term patent plus the Iso-3166 country code as the key. Note that only a small number of patent keys is defined by default, mainly to illustrate this scheme. These keys are used in the type field of @patent entries.

```
The generic term 'patent'.
  patent
          The expression 'German patent'.
patentde
          The expression 'European patent'.
patenteu
          The expression 'French patent'.
patentfr
          The expression 'British patent'.
patentuk
          The expression 'U.S. patent'.
patentus
          Patent requests are handled in a similar way, using the string patreq as the base name
          of the key:
          The generic term 'patent request'.
patregde
          The expression 'German patent request'.
         The expression 'European patent request'.
patregeu
          The expression 'French patent request'.
patregfr
         The expression 'British patent request'.
patrequk
          The expression 'U.S. patent request'.
patrequs
```

# 4.10 格式化命令 Formatting Commands

This section corresponds to § 3.9 in the user part of this manual. Bibliography and citation styles should incorporate the commands and facilities discussed in this section in order to provide a certain degree of high-level configurability. Users should not be forced to write new styles if all they want to do is modify the spacing in the bibliography or the punctuation used in citations.

# 4.10.1 用户可定义的命令和钩子 User-definable Commands and Hooks

This section corresponds to § 3.9.1 in the user part of the manual. The commands and hooks discussed here are meant to be redefined by users, but bibliography and citation styles may provide a default definition which is different from the package default. These commands are defined in biblatex.def. Note that all commands starting with  $\mbox{mk...}$  take one mandatory argument.

\bibnamedelima

This delimiter controls the spacing between the elements which make up a name part. It is inserted automatically by the backend after the first name element if the element is less than three characters long and before the last element. The default definition is \addhighpenspace, i. e., a space penalized by the value of the highnamepenalty counter (§ 3.9.3). Please refer to § 3.12.4 for further details.

Biber only

\bibnamedelimb	This delimiter controls the spacing between the elements which make up a name part. It is inserted automatically by the backend between all name elements where \bibnamedelima does not apply. The default definition is \addlowpenspace, i. e., a space penalized by the value of the lownamepenalty counter (§ 3.9.3). Please refer to § 3.12.4 for further details.	Biber only
\bibnamedelimc	This delimiter controls the spacing between name parts. The default name formats use it between the name prefix and the last name if useprefix=true. The default definition is \addhighpenspace, i.e., a space penalized by the value of the highnamepenalty counter (§ 3.9.3). Please refer to § 3.12.4 for further details.	
\bibnamedelimd	This delimiter controls the spacing between name parts. The default name formats use it between all name parts where \bibnamedelimc does not apply. The default definition is \addlowpenspace, i.e., a space penalized by the value of the lownamepenalty counter (§ 3.9.3). Please refer to § 3.12.4 for further details.	
\bibnamedelimi	This delimiter replaces \bibnamedelima/b after initials. Note that this only applies to initials given as such in the bib file, not to the initials automatically generated by Biblatex which use their own set of delimiters.	Biber only
\bibinitperiod	The punctuation inserted automatically by the backend after all initials unless \bibinithyphendelim applies. The default definition is a period (\addot). Please refer to § 3.12.4 for further details.	Biber only
\bibinitdelim	The spacing inserted automatically by the backend between multiple initials unless \bibinithyphendelim applies. The default definition is an unbreakable interword space. Please refer to § 3.12.4 for further details.	Biber only
\bibinithypheno	The punctuation inserted automatically by the backend between the initials of hyphenated name parts, replacing \bibinitperiod and \bibinitdelim. The default definition is a period followed by an unbreakable hyphen. Please refer to § 3.12.4 for further details.	Biber only
\bibindexnamede	elima Replaces \bibnamedelima in the index.	
\bibindexnamede	elimb Replaces \bibnamedelimb in the index.	
\bibindexnamede	elimc Replaces \bibnamedelimc in the index.	
\bibindexnamede	elimd Replaces \bibnamedelimd in the index.	
\bibindexnamede	elimi Replaces \bibnamedelimi in the index.	
\bibindexinitpe	eriod Replaces \bibinitperiod in the index.	
\bibindexinitdelim Replaces \bibinitdelim in the index.		

 $\verb|\bibindexinithyphendelim| Replaces \verb|\bibinithyphendelim| in the index.$ 

- \revsdnamepunct The punctuation to be printed between the first and last name parts when a name is reversed. The default is a comma. This command should be incorporated in formatting directives for name lists. Please refer to § 3.12.4 for further details.
  - \bibnamedash The dash to be used as a replacement for recurrent authors or editors in the bibliography. The default is an 'em' or an 'en' dash, depending on the indentation of the list of references.
- \labelnamepunct The separator to be printed after the name used for alphabetizing in the bibliography
  (author or editor, if the author field is undefined). Use this separator instead of
  \newunitpunct at this location. The default is \newunitpunct, i. e., it is not handled differently from regular unit punctuation but permits convenient reconfiguration.
- \subtitlepunct The separator to be printed between the fields title and subtitle, booktitle and booksubtitle, as well as maintitle and mainsubtitle. Use this separator instead of \newunitpunct at this location. The default is \newunitpunct, i. e., it is not handled differently from regular unit punctuation but permits convenient reconfiguration.
- \intitlepunct The separator to be printed between the word "in" and the following title in entry types such as @article, @inbook, @incollection, etc. Use this separator instead of \newunitpunct at this location. The default definition is a colon plus an interword space.
- \bibpagespunct The separator to be printed before the pages field. Use this separator instead of \newunitpunct at this location. The default is a comma plus an interword space.
- \bibpagerefpunct The separator to be printed before the pageref field. Use this separator instead of \newunitpunct at this location. The default is an interword space.
- \multinamedelim The delimiter to be printed between multiple items in a name list like author or editor if there are more than two names in the list. If there are only two names in the list, use the \finalnamedelim instead. This command should be incorporated in all formatting directives for name lists.
- \finalnamedelim Use this command instead of \multinamedelim before the final name in a name list.
- \revsdnamedelim The extra delimiter to be printed after the first name in a name list (in addition to \finalnamedelim) if the first name is reversed. This command should be incorporated in all formatting directives for name lists.
- \andothersdelim The delimiter to be printed before the localization string 'andothers' if a name list like author or editor is truncated. This command should be incorporated in all formatting directives for name lists.

- \multilistdelim The delimiter to be printed between multiple items in a literal list like publisher or location if there are more than two names in the list. If there are only two items in the list, use the \finallistdelim instead. This command should be incorporated in all formatting directives for literal lists.
- \finallistdelim Use this command instead of \multilistdelim before the final item in a literal list
- \andmoredelim The delimiter to be printed before the localization string 'andmore' if a literal list like publisher or location is truncated. This command should be incorporated in all formatting directives for literal lists.
- \multicitedelim The delimiter printed between citations if multiple entry keys are passed to a single citation command. This command should be incorporated in the definition of all citation commands, for example in the \setminus epcode argument passed to \DeclareCiteCommand. See § 4.3.1 for details.
- \supercitedelim Similar to \multinamedelim, but intended for the \supercite command only.
- \compcitedelim Similar to \multicitedelim, but intended for citation styles that 'compress' multiple citations, i. e., print the author only once if subsequent citations share the same author etc.
- \textcitedelim Similar to \multicitedelim, but intended for \textcite and related commands (§ 3.7.2).
- \nametitledelim The delimiter to be printed between the author/editor and the title. This command should be incorporated in the definition of all citation commands of author-title and some verbose citation styles.
- \nameyeardelim The delimiter to be printed between the author/editor and the year. This command should be incorporated in the definition of all citation commands of author-year citation styles.
- \volcitedelim The delimiter to be printed between the volume portion and the page/text portion of \volcite and related commands (§ 3.7.6).
- \prenotedelim The delimiter to be printed after the \( \lambda prenote \rangle \) argument of a citation command.
- \postnotedelim The delimiter to be printed after the  $\langle postnote \rangle$  argument of a citation command.
- \mkbibnamelast{ $\langle text \rangle$ } Formatting hook for the last name, to be used in all formatting directives for name lists.
- \mkbibnamefirst{\langle (text)} Similar to \mkbibnamelast, but intended for the first name.
- $\mbox{mkbibnameprefix} \{\langle \textit{text} \rangle\}$  Similar to  $\mbox{mkbibnamelast}$ , but intended for the name prefix.
- \mkbibnameaffix  $\{\langle text \rangle\}$  Similar to \mkbibnamelast, but intended for the name affix.

\relatedpunct The separator between the relatedtype bibliography localization string and the data from the first related entry.

\relateddelim The separator between the data of multiple related entries. The default definition is a linebreak.

# 4.10.2 不同语言的命令 Language-specific Commands

This section corresponds to § 3.9.2 in the user part of the manual. The commands discussed here are usually handled by the localization modules, but may also be redefined by users on a per-language basis. Note that all commands starting with \mk... take one or more mandatory arguments.

\bibrangedash The language specific range dash.

\bibdatedash The language specific date range dash.

\mkbibdatelong Takes the names of three field as arguments which correspond to three date components (in the order year/month/day) and uses their values to print the date in the language specific long date format.

\mkbibdateshort Similar to \mkbibdatelong but using the language specific short date format.

\finalandcomma Prints the comma to be inserted before the final 'and' in an enumeration, if applicable in the respective language.

\finalandsemicolon Prints the semicolon to be inserted before the final 'and' in an enumeration, if applicable in the respective language.

 $\mbox{\mbox{mkbibordinal}} \langle \mbox{\it integer} \rangle$ 

Takes an integer argument and prints it as an ordinal number.

 $\mbox{\mbox{$\$ 

Similar to \mkbibordinal, but prints a masculine ordinal, if applicable in the respective language.

\mkbibfemord{\langle integer\rangle}

Similar to \mkbibordinal, but prints a feminine ordinal, if applicable in the respective language.

\mkbibneutord{\langle integer\rangle}

Similar to \mkbibordinal, but prints a neuter ordinal, if applicable in the respective language.

 $\mbox{\mbox{$\$ 

Similar to \mkbibordinal, but intended for use with the term 'edition'.

\mkbibordseries{\langle integer\rangle}

Similar to \mkbibordinal, but intended for use with the term 'series'.

#### 4.10.3 用户可定义的尺寸和计数器 User-definable Lengths and Counters

This section corresponds to § 3.9.3 in the user part of the manual. The length registers and counters discussed here are meant to be altered by users. Bibliography and citation styles should incorporate them where applicable and may also provide a default setting which is different from the package default.

- \bibhang The hanging indentation of the bibliography, if applicable. This length is initialized to \parindent at load-time. If \parindent is zero length for some reason, \bibhang will default to 1em.
- \biblabelsep The horizontal space between entries and their corresponding labels. Bibliography styles which use list environments and print a label should set \labelsep to \biblabelsep in the definition of the respective environment.
- \bibitemsep The vertical space between the individual entries in the bibliography. Bibliography styles using list environments should set \itemsep to \bibitemsep in the definition of the respective environment.
- \bibparsep The vertical space between paragraphs within an entry in the bibliography. Bibliography styles using list environments should set \parsep to \bibparsep in the definition of the respective environment.
- abbrvpenalty The penalty used by \addabbrvspace, \addabthinspace, and \adddotspace, see § 4.7.4 for details.
- lownamepenalty The penalty used by \addlowpenspace and \addlpthinspace, see § 4.7.4 for details.
- highnamepenalty The penalty used by \addhighpenspace and \addhpthinspace, see § 4.7.4 for details.
- biburlnumpenalty If this counter is set to a value greater than zero, Biblatex will permit linebreaks after numbers in all strings formatted with the \url command from the url package. This will affect urls and does in the bibliography. The breakpoints will be penalized by the value of this counter. If urls and/or does in the bibliography run into the margin, try setting this counter to a value greater than zero but less than 10000 (you normally want to use a high value like 9000). Setting the counter to zero disables this feature. This is the default setting.
- biburlucpenalty Similar to biburlnumpenalty, except that it will add a breakpoint after all uppercase letters.

biburllcpenalty Similar to biburlnumpenalty, except that it will add a breakpoint after all lowercase letters.

# 4.10.4 辅助命令和钩子 Auxiliary Commands and Hooks

The auxiliary commands and facilities in this section serve a special purpose. Some of them are used by Biblatex to communicate with bibliography and citation styles in some way or other.

#### $\mathbb{C} \left( text \right)$

A generic command which prints its argument as emphasized text. This is a simple wrapper around the standard \emph command. Apart from that, it uses \setpunctfont from § 4.7.1 to adapt the font of the next punctuation mark following the text set in italics. If the punctfont package option is disabled, this command behaves like \emph.

# \mkbibitalic $\{\langle text \rangle\}$

Similar in concept to \mkbibemph but prints italicized text. This is a simple wrapper around the standard \textit command which incorporates \setpunctfont. If the punctfont package option is disabled, this command behaves like \textit.

#### $\mbox{mkbibbold} \{\langle text \rangle\}$

Similar in concept to \mkbibemph but prints bold text. This is a simple wrapper around the standard \textbf command which incorporates \setpunctfont. If the punctfont package option is disabled, this command behaves like \textbf.

#### $\mbox{\mbox{$\mbox{mkbibquote}} (\mbox{$\mbox{$text$}$})}$

A generic command which wraps its argument in quotation marks. If the csquotes package is loaded, this command uses the language sensitive quotation marks provided by that package. \mkbibquote also supports 'American-style' punctuation, see \DeclareQuotePunctuation in § 4.7.5 for details.

# \mkbibparens $\{\langle text \rangle\}$

A generic command which wraps its argument in parentheses. This command is nestable. When nested, it will alternate between parentheses and brackets, depending on the nesting level.

#### $\mbox{\mbox{mkbibbrackets}} \langle \mbox{\mbox{\it mkbibbrackets}} \langle \mbox{\it text} \rangle \}$

A generic command which wraps its argument in square brackets. This command is nestable. When nested, it will alternate between brackets and parentheses, depending on the nesting level.

#### \bibopenparen(text)\bibcloseparen

Alternative syntax for \mkbibparens. This will also work across groups. Note that \bibopenparen and \bibcloseparen must always be balanced.

### \bibopenbracket\langle text\rangle\bibclosebracket

Alternative syntax for \mkbibbrackets. This will also work across groups. Note that \bibopenbracket and \bibclosebracket must always be balanced.

# $\mbox{\mbox{$\mbox{$\mbox{$}$}}} \mbox{\mbox{$\mbox{$}$}} \mbox{\mbox{\mbox{$}$}} \mbox{\mbox{$\mbox{$}$}} \mbox{\mbox{$

A generic command which prints its argument as a footnote. This is a wrapper around the standard LaTeX \footnote command which removes spurious white-space preceding the footnote mark and prevents nested footnotes. By default, \mkbibfootnote requests capitalization at the beginning of the note and automatically adds a period at the end. You may change this behavior by redefining the \bibfootnotewrapper macro introduced below.

#### \mkbibfootnotetext $\{\langle text \rangle\}$

Similar to \mkbibfootnote but uses the \footnotetext command.

#### \mkbibendnote $\{\langle text \rangle\}$

Similar in concept to \mkbibfootnote except that it prints its argument as an endnote. \mkbibendnote removes spurious whitespace preceding the endnote mark
and prevents nested notes. It supports the \endnote command provided by the
endnotes package as well as the \pagenote command provided by the pagenote
package and the memoir class. If both commands are available, \endnote takes
precedence. If no endnote support is available, \mkbibendnote issues an error and
falls back to \footnote. By default, \mkbibendnote requests capitalization at the
beginning of the note and automatically adds a period at the end. You may change this
behavior by redefining the \bibendnotewrapper macro introduced below.

#### \mkbibendnotetext $\{\langle text \rangle\}$

Similar to \mkbibendnote but uses the \endnotetext command. Please note that as of this writing, neither the pagenote package nor the memoir class provide a corresponding \pagenotetext command. In this case, \mkbibendnote will issue an error and fall back to \footnotetext.

#### \bibfootnotewrapper $\{\langle text \rangle\}$

An inner wrapper which encloses the  $\langle text \rangle$  argument of \mkbibfootnote and \mkbibfootnotetext. For example, \mkbibfootnote eventually boils down to this:

```
\footnote{\bibfootnotewrapper{text}}
```

The wrapper ensures capitalization at the beginning of the note and adds a period at the end. The default definition is:

```
\newcommand{\bibfootnotewrapper}[1]{\bibsentence #1\addperiod}
```

If you don't want capitalization at the beginning or a period at the end of the note, do not modify \mkbibfootnote but redefine \bibfootnotewrapper instead.

```
\bibendnotewrapper\{\langle text \rangle\}
```

Similar in concept to \bibfootnotewrapper but related to the \mkbibendnote and \mkbibendnotetext commands.

```
\mbox{\ \ } \mbo
```

A generic command which prints its argument as superscripted text. This is a simple wrapper around the standard LaTeX \textsuperscript command which removes spurious whitespace and allows hyphenation of the preceding word.

```
\mkbibmonth{\langle integer\rangle}
```

This command takes an integer argument and prints it as a month name. Even though the output of this command is language specific, its definition is not, hence it is normally not redefined in localization modules.

```
\mkdatezeros{\langle integer\rangle}
```

This command strips leading zeros from a number or preserves them, depending on the datezeros package option (§ 3.1.2.1). It is intended for use in the definition of date formatting macros.

```
\stripzeros{\langle integer\rangle}
```

This command strips leading zeros from a number. It is intended for date formatting and ordinals.

shorthandwidth BibTeX only

A special field formatting directive which is used internally by Biblatex. When the bibliographic data is read from the bbl file, Biblatex measures the values of all shorthand fields and sets the length register \shorthandwidth to the width of the widest shorthand (see § 4.10.5). In order to determine the correct width, the package considers two factors: the definition of \bibfont and this formatting directive. All styles should adjust this directive such that it corresponds to the format used in the list of shorthands.

'labelfield' width Biber only

With Biber, for every field marked as a 'Label field' in the data model, a formatting directive is created as per shorthandwidth above. Since shorthand is so marked in the default data model, this functionality is a superset of that described for shorthandwidth.

labelnumberwidth Similar to shorthandwidth, but referring to the labelnumber field and the length register \labelnumberwidth. Numeric styles should adjust this directive such that it corresponds to the format used in the bibliography.

labelalphawidth Similar to shorthandwidth, but referring to the labelalpha field and the length register \labelalphawidth. Alphabetic styles should adjust this directive such that it corresponds to the format used in the bibliography.

bibhyperref A special formatting directive for use with \printfield and \printtext. This directive wraps its argument in a \bibhyperref command, see § 4.6.4 for details.

bibhyperlink A special formatting directive for use with \printfield and \printtext. It wraps its argument in a \bibhyperlink command, see § 4.6.4 for details. The  $\langle name \rangle$  argument passed to \bibhyperlink is the value of the entrykey field.

bibhypertarget A special formatting directive for use with \printfield and \printtext. It wraps its argument in a \bibhypertarget command, see § 4.6.4 for details. The  $\langle name \rangle$  argument passed to \bibhypertarget is the value of the entrykey field.

volcitepages A special formatting directive which controls the format of the page/text portion in the argument of citation commands like \volcite.

volcitevolume A special formatting directive which controls the format of the volume portion in the argument of citation commands like \volcite.

date A special formatting directive which controls the format of \printdate (§ 4.4.1). Note that the date format (long/short etc.) is controlled by the package option date from § 3.1.2.1. This formatting directive only controls additional formatting such as fonts etc.

datelabel Similar to date but controls the format of \printdatelabel.

urldate Similar to date but controls the format of \printurldate.

origdate Similar to date but controls the format of \printorigdate.

eventdate Similar to date but controls the format of \printeventdate.

# 4.10.5 辅助长度计数器和其它功能 Auxiliary Lengths, Counters, and Other Features

The length registers and counters discussed here are used by Biblatex to pass information to bibliography and citation styles. Think of them as read-only registers. Note that all counters are LaTeX counters. Use \value{counter} to read out the current value.

\shorthandwidth BibTeX only

This length register indicates the width of the widest shorthand. Bibliography styles should incorporate this length in the definition of the list of shorthands, if applicable.

\`labelfield'width Biber only

With Biber, for every field marked as a 'Label field' in the data model, a length register is created as per shorthandwidth above. Since shorthand is so marked in the default data model, this functionality is a superset of that described for shorthandwidth.

\labelnumberwidth This length register indicates the width of the widest labelnumber. Numeric bibliography styles should incorporate this length in the definition of the bibliography environment.

\labelalphawidth This length register indicates the width of the widest labelalpha. Alphabetic bibliography styles should incorporate this length in the definition of the bibliography environment.

maxextraalpha This counter holds the highest number found in any extraalpha field.

maxextrayear This counter holds the highest number found in any extrayear field.

refsection This counter indicates the current refsection environment. When queried in a bibliography heading, the counter returns the value of the refsection option passed to \printbibliography.

refsegment This counter indicates the current refsegment environment. When queried in a bibliography heading, this counter returns the value of the refsegment option passed to \printbibliography.

maxnames This counter holds the setting of the maxnames package option.

minnames This counter holds the setting of the minnames package option.

maxitems This counter holds the setting of the maxitems package option.

minitems This counter holds the setting of the minitems package option.

instcount This counter is incremented by Biblatex for every citation as well as for every entry in the bibliography and bibliography lists. The value of this counter uniquely identifies a single instance of a reference in the document.

citetotal This counter, which is only available in the  $\langle loopcode \rangle$  of a citation command defined with \DeclareCiteCommand, holds the total number of valid entry keys passed to the citation command.

CiteCount This counter, which is only available in the  $\langle loopcode \rangle$  of a citation command defined with \DeclareCiteCommand, holds the number of the entry key currently being processed by the  $\langle loopcode \rangle$ .

multicitetotal This counter is similar to citetotal but only available in multicite commands. It holds the total number of citations passed to the multicite command. Note that each of these citations may consist of more than one entry key. This information is provided by the citetotal counter.

multicitecount This counter is similar to citecount but only available in multicite commands. It holds the number of the citation currently being processed. Note that this citation may consist of more than one entry key. This information is provided by the citetotal and citecount counters.

listtotal

This counter holds the total number of items in the current list. It is intended for use in list formatting directives and does not hold a meaningful value when used anywhere else. As an exception, it may also be used in the second optional argument to \printnames and \printlist, see § 4.4.1 for details. For every list, there is also a counter by the same name which holds the total number of items in the corresponding list. For example, the author counter holds the total number of items in the author list. This applies to both name lists and literal lists. These counters are similar to listtotal except that they may also be used independently of list formatting directives. For example, a bibliography style might check the editor counter to decide Whether or not to print the term "editor" or rather its plural form "editors" after the list of editors.

listcount This counter holds the number of the list item currently being processed. It is intended for use in list formatting directives and does not hold a meaningful value when used anywhere else.

liststart This counter holds the \( \start \) argument passed to \( \printnames or \) printlist. It is intended for use in list formatting directives and does not hold a meaningful value when used anywhere else.

liststop This counter holds the  $\langle stop \rangle$  argument passed to \printnames or \printlist. It is intended for use in list formatting directives and does not hold a meaningful value when used anywhere else.

\currentfield The name of the field currently being processed by \printfield. This information is only available locally in field formatting directives.

\currentlist

The name of the literal list currently being processed by \printlist. This information is only available locally in list formatting directives.

\currentname

The name of the name list currently being processed by \printnames. This information is only available locally in name formatting directives.

# 4.10.6 一般目的的钩子 General Purpose Hooks

#### $\AtBeginBibliography \{ \langle code \rangle \}$

Appends the  $\langle code \rangle$  to an internal hook executed at the beginning of the bibliography. The  $\langle code \rangle$  is executed at the beginning of the list of references, immediately after the (begin code) of \defbibenvironment. This command may only be used in the preamble.

### $\AtBeginShorthands{\langle code \rangle}$

Appends the  $\langle code \rangle$  to an internal hook executed at the beginning of the list of shorthands. The  $\langle code \rangle$  is executed at the beginning of the list of shorthands, immediately after the  $\langle begin\ code \rangle$  of \defbibenvironment. This command may only be used in the preamble.

When using Biber, this is just an alias for:

\AtBeginBiblist{shorthand}{code}

# $\AtBeginBiblist{\langle biblistname \rangle} {\langle code \rangle}$

Biber only

Appends the  $\langle code \rangle$  to an internal hook executed at the beginning of the bibliography list  $\langle biblistname \rangle$ . The  $\langle code \rangle$  is executed at the beginning of the bibliography list, immediately after the  $\langle begin\ code \rangle$  of \defbibenvironment. This command may only be used in the preamble.

#### $\AtEveryBibitem{\langle code \rangle}$

Appends the  $\langle code \rangle$  to an internal hook executed at the beginning of every item in the bibliography. The  $\langle code \rangle$  is executed immediately after the  $\langle item\ code \rangle$  of \defbibenvironment. The bibliographic data of the respective entry is available at this point. This command may only be used in the preamble.

#### $\AtEveryLositem{\langle code \rangle}$

Appends the  $\langle code \rangle$  to an internal hook executed at the beginning of every item in the list of shorthands. The  $\langle code \rangle$  is executed immediately after the  $\langle item\ code \rangle$  of \defbibenvironment. The bibliographic data of the respective entry is available at this point. This command may only be used in the preamble.

When using Biber, this is just an alias for:

\AtEveryBiblistitem{shorthand}{code}

#### \AtEveryBiblistitem{\langle biblistname \rangle} \{\langle code \rangle}

Biber only

Appends the  $\langle code \rangle$  to an internal hook executed at the beginning of every item in the bibliography list named  $\langle biblistname \rangle$ . The  $\langle code \rangle$  is executed immediately after the  $\langle item\ code \rangle$  of  $\defbibenvironment$ . The bibliographic data of the respective entry is available at this point. This command may only be used in the preamble.

#### $\AtNextBibliography{\langle code \rangle}$

Similar to \AtBeginBibliography but only affecting the next \printbibliography. The internal hook is cleared after being executed once. This command may be used in the document body.

#### $AtEveryCite{\langle code \rangle}$

Appends the  $\langle code \rangle$  to an internal hook executed at the beginning of every citation command. The  $\langle code \rangle$  is executed immediately before the  $\langle precode \rangle$  of the command (see § 4.3.1). No bibliographic data is available at this point. This command may only be used in the preamble.

### $\AtEveryCitekey{\langle code \rangle}$

Appends the  $\langle code \rangle$  to an internal hook executed once for every entry key passed to a citation command. The  $\langle code \rangle$  is executed immediately before the  $\langle loopcode \rangle$  of the command (see § 4.3.1). The bibliographic data of the respective entry is available at this point. This command may only be used in the preamble.

# $AtEveryMultiCite{\langle code \rangle}$

Appends the  $\langle code \rangle$  to an internal hook executed at the beginning of every multicite command. The  $\langle code \rangle$  is executed immediately before the multiprenote field (§ 4.3.2) is printed. No bibliographic data is available at this point. This command may only be used in the preamble.

# $\AtNextCite{\langle code \rangle}$

Similar to \AtEveryCite but only affecting the next citation command. The internal hook is cleared after being executed once. This command may be used in the document body.

#### $\AtNextCitekey{\langle code \rangle}$

Similar to \AtEveryCitekey but only affecting the next entry key. The internal hook is cleared after being executed once. This command may be used in the document body.

#### $\AtNextMultiCite{\langle code \rangle}$

Similar to \AtEveryMultiCite but only affecting the next multicite command. The internal hook is cleared after being executed once. This command may be used in the document body.

# \AtDataInput[\langle entrytype \rangle] \{ \langle code \rangle \}

Appends the  $\langle code \rangle$  to an internal hook executed once for every entry as the bibliographic data is imported from the bbl file. The  $\langle entrytype \rangle$  is the entry type the  $\langle code \rangle$  applies to. If it applies to all entry types, omit the optional argument. The  $\langle code \rangle$  is executed immediately after the entry has been imported. This command may only be used in the preamble. Note that  $\langle code \rangle$  may be executed multiple times for an entry. This occurs when the same entry is cited in different refsection environments or the sorting option settings incorporate more than one sorting scheme. The refsection counter holds the number of the respective reference section while the data is imported.

#### \UseBibitemHook

Executes the internal hook corresponding to \AtEveryBibitem.

#### \UseEveryCiteHook

Executes the internal hook corresponding to \AtEveryCite.

#### \UseEveryCitekeyHook

Executes the internal hook corresponding to \AtEveryCitekey.

### \UseEveryMultiCiteHook

Executes the internal hook corresponding to \AtMultiEveryCite.

#### \UseNextCiteHook

Executes and clears the internal hook corresponding to \AtNextCite.

#### \UseNextCitekeyHook

Executes and clears the internal hook corresponding to  $\AtNextCitekey$ .

#### \UseNextMultiCiteHook

Executes and clears the internal hook corresponding to  $\AtNextMultiCite$ .

#### \DeferNextCitekeyHook

Locally un-defines the internal hook specified by  $\AtNextCitekey$ . This essentially defers the hook to the next entry key in the citation list, when executed in the  $\langle precode \rangle$  argument of  $\DeclareCiteCommand$  (§ 4.3.1).

# 4.11 提示与警告 Hints and Caveats

This section provides some additional hints concerning the author interface of this package. It also addresses common problems and potential misconceptions.

#### 4.11.1 条目集 Entry Sets

Entry sets have already been introduced in § 3.11.5. This section discusses how to process entry sets in a bibliography style. From the perspective of the driver, there is no difference between static and dynamic entry sets. Both types are handled in the same way. You will normally use the \entryset command from § 4.4.1 to loop over all set members (in the order in which they are listed in the entryset field of the @set entry, or in the order in which they were passed to \defbibentryset, respectively) and append \finentry at the end. That's it. The formatting is handled by the drivers for the entry types of the individual set members:

```
\DeclareBibliographyDriver{set}{%
  \entryset{}{}%
  \finentry}
```

You may have noticed that the numeric styles which ship with this package support subdivided entry sets, i.e., the members of the set are marked with a letter or some other marker such that citations may either refer to the entire set or to a specific set member. The markers are generated as follows by the bibliography style:

```
\DeclareBibliographyDriver{set} {%
  \entryset
     {\printfield{entrysetcount}%
     \setunit*{\addnbspace}}
     {}%
  \finentry}
```

The entrysetcount field holds an integer indicating the position of a set member in the entry set. The conversion of this number to a letter or some other marker is handled by the formatting directive of the entrysetcount field. All the driver needs to do is print the field and add some white space (or start a new line). Printing the markers in citations works in a similar way. Where a numeric style normally says \printfield{labelnumber}, you simply append the entrysetcount field:

```
\printfield{labelnumber}\printfield{entrysetcount}
```

Since this field is only defined when processing citations referring to a set member, there is no need to add any additional tests.

#### 4.11.2 电子出版信息 Electronic Publishing Information

The standard styles feature dedicated support for arXiv references. Support for other resources is easily added. The standard styles handle the eprint field as follows:

```
\iffieldundef{eprinttype}
    {\printfield{eprint}}
    {\printfield[eprint:\strfield{eprinttype}] {eprint}}
```

If an eprinttype field is available, the above code tries to use the field format eprint: \( \left( eprinttype \right) \). If this format is undefined, \( \right( printfield \) automatically falls back to the field format eprint. There are two predefined field formats, the type-specific format eprint: \( \arxiv \) and the fallback format eprint:

```
\DeclareFieldFormat{eprint}{...}
\DeclareFieldFormat{eprint:arxiv}{...}
```

In other words, adding support for additional resources is as easy as defining a field format named eprint:  $\langle resource \rangle$  where  $\langle resource \rangle$  is an identifier to be used in the eprinttype field.

#### 4.11.3 额外的摘要和注释 External Abstracts and Annotations

External abstracts and annotations have been discussed in § 3.11.8. This section provides some more background for style authors. The standard styles use the following macros (from biblatex.def) to handle abstracts and annotations:

```
\newbibmacro*{annotation}{%
   \iffieldundef{annotation}
   {\printfile[annotation] {\bibannotationprefix\thefield{entrykey}.tex}}%
   {\printfield{annotation}}}
\newcommand*{\bibannotationprefix}{bibannotation-}

\newbibmacro*{abstract}{%
   \iffieldundef{abstract}
   {\printfile[abstract] {\bibabstractprefix\thefield{entrykey}.tex}}%
   {\printfield{abstract}}}

\newcommand*{\bibabstractprefix}{bibabstractprefix}{bibabstract-}
```

If the abstract/annotation field is undefined, the above code tries to load the abstracts/annotations from an external file. The \printfile commands also incorporate file name prefixes which may be redefined by users. Note that you must enable \printfile explicitly by setting the loadfiles package option from § 3.1.2.1. This feature is disabled by default for performance reasons.

# 4.11.4 消除姓名歧义 Name Disambiguation

Biber only

在§3.1.2.3节引入的uniquename和uniquelist选项支持多种操作模式。本节用举例方式介绍不同模式的差别。uniquename选项消除labelname列表中各姓名间的歧义,uniquelist消除因maxnames/minnames截短导致的labelname列表歧义。两个选项可以单独使用也可以联合使用:

**4.11.4.1 单个姓名 (姓名内的处理) (uniquename)** 下面从一些uniquename例 子开始,考虑如下数据:

```
John Doe 2008
Edward Doe 2008
John Smith 2008
Jane Smith 2008
```

假设我们使用作者年制且设置 uniquename=false,这种情况下,我们得到如下引用标注:

```
Doe 2008a
Doe 2008b
Smith 2008a
Smith 2008b
```

因为姓有歧义,且所有的年都相同,所以年后附加的字符用来区分并消除歧 义。然而,很多样式指南强制要求附加字符只能用于相同作者的区分,而不能用于 作者相同的姓的区分。为了消除作者姓的歧义,需要增加姓名的其它完整部分或者 缩写来区分。这一需要由uniquename选项处理,下面是使用了 uniquename= init 的引用标注:

J. Doe 2008 E. Doe 2008 Smith 2008a Smith 2008b

uniquename=init 限制了用缩写来区分姓名。但因为'J. Smith' 仍然有歧义, 所以没有增加。而使用 uniquename=full, 标注如下:

J. Doe 2008 E. Doe 2008 John Smith 2008 Jane Smith 2008

为了说明 uniquename=init/full 和 allinit/allfull 的差别,我 们下面介绍 'visible' 姓名的概念。'visible' 姓名时位于maxnames/minnames/ uniquelist截短点前的姓名,比如,给出数据:

William Jones/Edward Doe/Jane Smith John Doe John Smith

maxnames=1, minnames=1, uniquename=init/full, 我们得到如下的 引用标注:

Jones et al. Doe

Smith

在消除歧义的时候, uniquename=init/full 仅考虑可见的姓名。因为本 例中所有的可见姓名的姓都是不同的,所有没有姓名的其他部分附加进来。比较 一下使用 uniquename=allinit 的输出:

Jones et al. J. Doe

Smith

allinit 认为所有在labelname列表中的姓名,包括列表截短后已经隐藏 并且由'et al.' 代替的姓名。在本例中,'John Doe'与'Edward Doe'存在歧义。因 为两个'Smiths'无法通过添加缩写的方式区分,所以没有添加。现在来比较一下 uniquename=allfull 的输出:

Jones et al.

J. Doe

John Smith

uniquename=mininit/minfull 选项类似于 init/full 仅考虑可见姓名,但仅执行最小的歧义消除。即,仅对姓列表的歧义进行处理,考虑如下数据:

John Doe/William Jones
Edward Doe/William Jones
John Smith/William Edwards
Edward Smith/Allan Johnson

使用 uniquename=init/full, 得到:

- J. Doe and Jones
- E. Doe and Jones
- J. Smith and Edwards
- E. Smith and Johnson

使用 uniquename=mininit/minfull, 得到:

- J. Doe and Jones
- E. Doe and Jones

Smith and Edwards

Smith and Johnson

'Smiths'并无歧义,因为姓名列表时没有歧义。mininit/minfull选项仅对姓的列表相同情况进行处理。全局的看姓的列表,注意当未截短的列表的可见名相同的时候,截短的列表时也可能是不同的,比如下面的数据:

John Doe/William Jones Edward Doe

使用 maxnames=1, uniquename=init/full:

- J. Doe et al.
- E. Doe

使用 uniquename=mininit/minfull:

Doe et al.

Doe

因为列表有'et al.'的不同,姓名列表就不歧义。

**4.11.4.2 姓名列表 (独立姓名外的处理) (uniquelist)** 姓名列表也可能存在歧义问题。如果labelname列表由maxnames/minnames选项截短就可能产生歧义。这类问题由uniquelist选处理,考虑如下数据:

Doe/Jones/Smith 2005 Smith/Johnson/Doe 2005 Smith/Doe/Edwards 2005 Smith/Doe/Jones 2005

很多作者年制样式需要在标注中截短,比如使用 maxnames=1 选项,得到:

Doe et al. 2005 Smith et al. 2005a Smith et al. 2005b Smith et al. 2005c

因为截短后作者存在歧义,所以添加额外字符确保引用标注的唯一性。同样的,一些样式强制要求额外字符只能用于所有作者都相同的情况。为了区分作者列表,必须增加更多的姓名,这样就会超出maxnames/minnames选项设定的截短点。uniquelist选项即描述这一需求,当 uniquelist=true,有:

Doe et al. 2005 Smith, Johnson et al. 2005 Smith, Doe and Edwards 2005 Smith, Doe and Jones 2005

The uniquelist option overrides maxnames/minnames on a per-entry basis. Essentially, what happens is that the 'et al.' part of the citation is expanded to the point of no ambiguity – but no further than that. uniquelist may also be combined with uniquename. Consider the following data:

uniquelist选项以条目为限重设maxnames/minnames。大体上,标注的 'et al.' 部分扩展到无歧义的点-而且也基本到此为止。uniquelist也可以与uniquename联合使用,考虑如下数据:

John Doe/Allan Johnson/William Jones 2009
John Doe/Edward Johnson/William Jones 2009
John Doe/Jane Smith/William Jones 2009
John Doe/John Smith/William Jones 2009
John Doe/John Edwards/William Jones 2009
John Doe/John Edwards/Jack Johnson 2009

使用 maxnames=1, 得到:

Doe et al. 2009a Doe et al. 2009b Doe et al. 2009c Doe et al. 2009d Doe et al. 2009e Doe et al. 2009f

使用 maxnames=1, uniquename=full, uniquelist=true 则有:

Doe, A. Johnson et al. 2009
Doe, E. Johnson et al. 2009
Doe, Jane Smith et al. 2009
Doe, John Smith et al. 2009
Doe, Edwards and Jones 2009
Doe, Edwards and Johnson 2009

使用 uniquelist = minyear,消除列表歧义仅在可见列表和labelyear相同的时候。这对于仅仅需要整个标注整体具有唯一性的作者年制样式是很有用的,但是不保证作者姓名的非歧义性。这一模式概念上域uniquename=mininit/minfull选项相关。考虑如下例子:

Smith/Jones 2000 Smith/Johnson 2001

使用 maxnames=1 和 uniquelist=true, 得到:

Smith and Jones 2000 Smith and Johnson 2001

使用 uniquelist=minyear, 则得到:

Smith et al. 2000 Smith et al. 2001

使用 uniquelist=minyear,两个文献的作者是否相同并不清楚,但标注的整体是非歧义的,因为年份的不同。与此相反,uniquelist=true需要消除作者列表的歧义即便这一信息对于参考文献表的唯一引用是不必要的,看看如下例子:

Vogel/Beast/Garble/Rook 2000 Vogel/Beast/Tremble/Bite 2000 Vogel/Beast/Acid/Squeeze 2001

使用 maxnames=3, minnames=1, uniquelist=true, 得到

Vogel, Beast, Garble et al. 2000 Vogel, Beast, Tremble et al. 2000 Vogel, Beast, Acid et al. 2001 使用 uniquelist=minyear 选项,则有:

```
Vogel, Beast, Garble et al. 2000
Vogel, Beast, Tremble et al. 2000
Vogel et al. 2001
```

在最后一个引用中,uniquelist=minyear不重写maxnames/minnames,因为年份的不同,所以不需要消除与其它两个间的歧义。

# 4.11.5 浮动体和TOC/LOT/LOF中的追踪器 Trackers in Floats and TOC/LOT/LOF

If a citation is given in a float (typically in the caption of a figure or table), scholarly back references like 'ibidem' or back references based on the page tracker get ambiguous because floats are objects which are (physically and logically) placed outside the flow of text, hence the logic of such references applies poorly to them. To avoid any such ambiguities, the citation and page trackers are temporarily disabled in all floats. In addition to that, these trackers plus the back reference tracker (backref) are temporarily disabled in the table of contents, the list of figures, and the list of tables.

### 4.11.6 混合编程接口 Mixing Programming Interfaces

Biblatex 宏包给样式作者提供了 2 个主要的编程接口即: bbx文件中使用的\DeclareBibliographyDriver 命令用来定义各类参考文献条目的驱动(格式处理器, handler), cbx文件中使用的\DeclareCiteCommand命令用来定义新的引用命令。然而有时候,混合使用这两个接口会很方便。比如\fullcite命令就可以打印类似于完整参考文献条目的长串引用,该命令定义大体如下:

```
\DeclareCiteCommand{\fullcite}
{...}
{\usedriver{...}{\thefield{entrytype}}}
{...}
{...}
```

如上所见,打印引用的核心代码简单地为当前的条目类型执行了\DeclareBibliographyDriver定义的参考文献驱动命令。当为长引用样式 (a verbose citation scheme) 编写引用样式文件的时候,使用下面的结构是非常方便的:

```
\ProvidesFile{example.cbx}[2007/06/09 v1.0 biblatex citation style]
\DeclareCiteCommand{\cite}
{...}
{\usedriver{...}{cite:\thefield{entrytype}}}}
{...}
```

```
{...}
\DeclareBibliographyDriver{cite:article}{...}
\DeclareBibliographyDriver{cite:book}{...}
\DeclareBibliographyDriver{cite:inbook}{...}
...
```

混合接口的另一个有用情况是在参考文献表中使用交叉引用 (cross-references) 时。比如当打印@incollection 类型的条目,数据继承自@collection父条目,将会由一个简短的指向对应父条目的指针来代替。

- [1] Audrey Author: Title of article. In: [2], pp. 134–165.
- [2] Edward Editor, ed.: Title of collection. Publisher: Location, 1995.

实现这种参考文献的交叉引用的一种方法是认为他们是引用关系,使用xref或 crossref域的值作为条目关键字(bibtex条目键, entry key),例子如下:

```
\ProvidesFile{example.bbx}[2007/06/09 v1.0 biblatex bibliography style]

\DeclareCiteCommand{\bbx@xref}

{}
{...}% code for cross-references
{}
{}

\DeclareBibliographyDriver{incollection}{%

...
\iffieldundef{xref}

{...}% code if no cross-reference
{\bbx@xref{\thefield{xref}}}%

...
}
```

\ProvidesFile{example.bbx}[2007/06/09 v1.0 biblatex bibliography style]

```
\DeclareBibliographyDriver{incollection}{%

...
\iffieldundef{xref}

{...}% code if no cross-reference
{\entrydata{\thefield{xref}}}{%

% code for cross-references

...
}}%

...
}
```

#### 4.11.7 使用标点追踪 Using the Punctuation Tracker

**4.11.7.1 标点基础 The Basics** 样式作者设计参考文献驱动时需要记住一点: 块和单元的标点是异步处理的。用例子最容易解释这一点,看下面一段代码:

```
\printfield{title}%
\newunit
\printfield{edition}%
\newunit
\printfield{note}%
```

如果没有edition域,那么这段代码的打印结果不会是:

Title. . Note

而会是

Title. Note

因为单元的标点追踪器是异步方式工作的。\newunit命令将不会立即打印标点。它仅是记录一个单元的边界并且将\newunitpunct命令放入标点缓存中。该缓存会有接下来的\printfield、\printlist或类似命令进行处理,且仅当这些命令各自处理的域或列表已定义的时候才会处理。像\printfield这样的命令在插入任何块和单元的标点之前将首先考虑3个因素:

- 是否有新的单元/块的输出请求?
  - =前面是否有\newunit或者\newblock命令?
- 前面的命令是否有打印输出?
  - = 前面是否有\printfield或者相似命令?
  - = 该命令是否实际打印了任何东西?
- 现在是否要打印一些东西?要进行打印处理的域或列表是否已定义?

块和单元的标点只会在上述所有条件满足的时候才会输出。让我们再次考虑上面 的例子:

```
\printfield{title}%
\newunit
\printfield{edition}%
\newunit
\printfield{note}%
```

如果edition域没有定义会发生什么呢?第一个\printfield命令打印了标 题并设置一个内部的'new text'标志。第一个\newunit命令设置一个内部 的'new unit'标志。这使没有任何标点输出。第二个\printfield命令不进行任 何处理因为edition域未定义。接下来的\newunit命令再次设置'new unit'标 志,仍然没有标点输出。第三个\printfield命令检测note域是否已定义,如 果是,它会寻找'new text'和'new unit'标志。如果两个标志都存在,那么它会在打 印 note 前插入标点缓存。然后它会清除'new unit' 标志然后再次设置'new text' 标 志。

所有这些听起来似乎很复杂, 但实际上, 这意味着可以用顺序的方式写一个 具有很多部件的参考文献驱动。这种方法的优势在不使用标点追踪而实现上述代 码功能时会体现的很明显。如果不用标点追踪,那么会因为大量对所有可能存在 域的判断产生一个复杂的\iffieldundef判断命令集合。

```
\iffieldundef{title}%
  {\iffieldundef{edition}
     {\printfield{note}}
     {\printfield{edition}%
     \iffieldundef{note}%
        {. \printfield{note}}}
  {\printfield{title}%
   \iffieldundef{edition}
     {. \printfield{edition}}%
   \iffieldundef{note}
     {. \printfield{note}}}%
```

4.11.7.2 **常见错误 Common Mistakes** 把单元的标点处理认为是同步处理的是 一个相当常见的误解。这会导致当驱动中包含原样文本46时出现一些典型错误。考 虑下面导致标点错位的错误代码段:

```
\printfield{title}%
```

<sup>&</sup>lt;sup>46</sup>这里 literal text 理解为原样文本,如实文本,逐字文本

```
\newunit
(\printfield{series} \printfield{number})%
这段代码将产生下面的结果:
Title (. Series Number)
```

这里发生了什么呢?第一个\printfield命令打印了标题,然后\newunit命令标记了一个新的单元边界但不打印任何内容。单元的标点由下一个\printfield命令打印。这是前面提过的异步机制。然而因为左括号在下一个\printfield命令插入标点前立即打印,所以导致了错误的句点。当插入任何原样文本比如括号(还包括由\bibopenparen和\mkbibparens命令打印的括号)时,总需要将这些文本用\printtext命令包起来。要让标点追踪正常运转,需要让驱动知道所有插入的原样文本。这是\printtext命令的作用所在。\printtext命令联系标点追踪器确保标点缓存在原样文本打印前插入。它也设定内部'new text'标志。注意本例中还有第三处原样文本即\printfield{series}后面的空格。在改正的例子中,我们将使用标点追踪器来处理该空格。

```
\printfield{title}%
\newunit
\printtext{(}%
\printfield{series}%
\setunit*{\addspace}%
\printfield{number}%
\printtext{)}%
```

尽管上面的代码能够如常工作,但处理括号、引号和其它包围某个域的标点是,推 荐的方式是定义一个域格式:

```
\DeclareFieldFormat{parens}{\mkbibparens{#1}}
```

域格式可以同时用于\printfield和\printtext命令,因此我们可以利用它对若干个域用一堆括号进行包裹。

```
\printtext[parens] {%
  \printfield{series} %
  \setunit*{\addspace} %
  \printfield{number} %
} %
```

这里我们还需要处理没有 series 信息时的情况,因此进一步改进代码如下:

```
\iffieldundef{series}
{}
{\printtext[parens]{%
```

```
\printfield{series}%
\setunit*{\addspace}%
\printfield{number}}}%
```

最后的一点提示: 本地化字符串对于标点追踪器来说不是原样文本。因为\bibstring和相似命令能联系标点追踪器,因此就不需要用\printtext包裹起来。

**4.11.7.3 高级应用 Advanced Usage** 标点追踪器也可用来处理更复杂的情况。比如,考虑需要对location、publisher和 year根据数据是否提供以如下的格式打印:

```
...text. Location: Publisher, Year. Text...
...text. Location: Publisher. Text...
...text. Location: Year. Text...
...text. Publisher, Year. Text...
...text. Location. Text...
...text. Publisher. Text...
...text. Year. Text...
```

这个问题可以用一个相当复杂的\iflistundef和\iffieldundef判断集进行处理,通过这些判断可以确定所有可能的域的组合:

```
\iflistundef{location}
{\iflistundef{publisher}}
{\printfield{year}}
{\printlist{publisher}%
  \iffieldundef{year}
}}
{\printfield{year}}}
{\printlist{location}%
  \iflistundef{publisher}%
  {\iffieldundef{year}
    {}
    {: \printfield{year}}}
}
{: \printfield{year}}
{: \printlist{publisher}%
  \iffieldundef{year}
    {}
    {, \printfield{year}}
}
{; \printfieldundef{year}
    {}
    {}
    {}
}
```

可以应用\ifthenelse命令和 § 4.6.3讨论的布尔运算可使上面的代码更具可读性。但本质上是一样的。然而,也可以按顺序写成如下方式:

```
\newunit
\printlist{location}%
```

```
\setunit*{\addcolon\space}%
\printlist{publisher}%
\setunit*{\addcomma\space}%
\printfield{year}%
\newunit
```

在实际使用中,你会经常使用标点追踪器执行一些显式或隐式的组合判断,比如, 考虑如下格式 (注意当没有 publisher 时 location 后面的标点)

```
...text. Location: Publisher, Year. Text...
...text. Location: Publisher. Text...
...text. Location, Year. Text...
...text. Publisher, Year. Text...
...text. Location. Text...
...text. Publisher. Text...
...text. Year. Text...
这可以用如下代码进行处理:
\newunit
\printlist{location}%
\iflistundef{publisher}
  {\setunit*{\addcomma\space}}
  {\setunit*{\addcolon\space}}%
\printlist{publisher}%
\setunit*{\addcomma\space}%
\printfield{year}%
\newunit.
```

因为当没有 publisher 时 location 后面的标点的特殊性,我们需要用一个\iflistundef判断来确保正确性。剩下其它的则有标点追踪器处理。

#### 4.11.8 定制本地化模型 Custom Localization Modules

Style guides may include provisions as to how strings like 'edition' should be abbreviated or they may mandate certain fixed expressions. For example, the MLA style guide requires authors to use the term 'Works Cited' rather than 'Bibliography' or 'References' in the heading of the bibliography. Localization commands such as \DefineBibliographyStrings from § 3.8 may indeed be used in cbx and bbx files to handle such cases. However, overloading style files with translations is rather inconvenient. This is where \DeclareLanguageMapping from § 4.9.1 comes into play. This command maps an lbx file with alternative translations to a babel/polyglossia language. For example, you could create a file named french-humanities.lbx which provides French translations adapted for use in the humanities and map it to the babel/polyglossia language french in the preamble or in the configuration file:

```
\DeclareLanguageMapping{french} {french-humanities}
```

If the document language is set to french, french-humanities.lbx will replace french.lbx. Coming back to the MLA example mentioned above, an MLA style may come with an american-mla.lbx file to provide strings which comply with the MLA style guide. It would declare the following mapping in the cbx and/or bbx file:

```
\DeclareLanguageMapping{american} {american-mla}
```

Since the alternative lbx file can inherit strings from the standard american.lbx module, american-mla.lbx may be as short as this:

Alternative lbx files must ensure that the localization module is complete. They will typically do so by inheriting data from the corresponding standard module. If the language american is mapped to american-mla.lbx, Biblatex will not load american.lbx unless this module is requested explicitly. In the above example, inheriting 'strings' and 'extras' will cause Biblatex to load american.lbx before applying the modifications in american-mla.lbx.

Note that \DeclareLanguageMapping is not intended to handle language variants (e.g., American English vs. British English) or babel/polyglossia language aliases (e.g., USenglish vs. american). For example, babel/polyglossia offers the USenglish option which is similar to american. Therefore, Biblatex ships with an USenglish.lbx file which simply inherits all data from american.lbx (which in turn gets the 'strings' from english.lbx). In other words, the mapping of language variants and babel/polyglossia language aliases happens on the file level, the point being that Biblatex's language support can be extended simply by adding additional 1bx files. There is no need for centralized mapping. If you need support for, say, Portuguese (babel/polyglossia: portuges), you create a file named portuges.lbx. If babel/polyglossia offered an alias named brasil, you would create brasil.lbx and inherit the data from portuges.lbx. In contrast to that, the point of \DeclareLanguageMapping is handling stylistic variants like 'humanities vs. natural sciences' or 'MLA vs. APA' etc. which will typically be built on top of existing lbx files.

### 4.11.9 编组 Grouping

In a citation or bibliography style, you may need to set flags or store certain values for later use. In this case, it is crucial to understand the basic grouping structure imposed by this package. As a rule of thumb, you are working in a large group whenever author commands such as those discussed in § 4.6 are available because the author interface of this package is only enabled locally. If any bibliographic data is available, there is at least one additional group. Here are some general rules:

- The entire list of references printed by \printbibliography and similar commands is processed in a group. Each entry in the list is processed in an additional group which encloses the \( \lambda item code \rangle \) of \defbibenvironment as well as all driver code.
- The entire bibliography list printed by \printbiblist is processed in a group. Each entry in the list is processed in an additional group which encloses the \(\langle item code \rangle \) of \defbibenvironment as well as all driver code.
- All citation commands defined with \DeclareCiteCommand are processed in a group holding the complete citation code consisting of the \langle precode \rangle, \langle sepcode \rangle, \langle loopcode \rangle, and \langle postcode \rangle arguments. The \langle loopcode \rangle is enclosed in an additional group every time it is executed. If any \langle wrapper \rangle code has been specified, the entire unit consisting of the wrapper code and the citation code is wrapped in an additional group.
- In addition to the grouping imposed by all backend commands defined with \DeclareCiteCommand, all 'autocite' and 'multicite' definitions imply an additional group.
- \printfile, \printtext, \printfield, \printlist, and \printnames form groups. This implies that all formatting directives will be processed within a group of their own.
- All lbx files are loaded and processed in a group. If an lbx file contains any
  code which is not part of \DeclareBibliographyExtras, the definitions
  must be global.

Note that using \aftergroup in citation and bibliography styles is unreliable because the precise number of groups employed in a certain context may change in future versions of this package. If the above list states that something is processed in a group, this means that there is *at least one* group. There may also be several nested ones.

# 4.11.10 命名空间 Namespaces

In order to minimize the risk of name clashes, LaTeX packages typically prefix the names of internal macros with a short string specific to the package. For example,

if the foobar package requires a macro for internal use, it would typically be called \FB@macro or \foo@macro rather than \macro or \@macro. Here is a list of the prefixes used or recommended by Biblatex:

- All macros with names like \blx@name are strictly reserved for internal use. This also applies to counter names, length registers, boolean switches, and so on. These macros may be altered in backwards-incompatible ways, they may be renamed or even removed at any time without further notice. Such changes will not even be mentioned in the revision history or the release notes. In short: never use any macros with the string blx in their name in any styles.
- abx Macros prefixed with abx are also internal macros but they are fairly stable. It is always preferable to use the facilities provided by the official author interface, but there may be cases in which using an abx macro is convenient.
- bbx This is the recommended prefix for internal macros defined in bibliography styles.
- cbx This is the recommended prefix for internal macros defined in citation styles.
- This is the recommended base prefix for internal macros defined in localization modules. The localization module should add a second prefix to specify the language. For example, an internal macro defined by the Spanish localization module would be named \lbx@es@macro.

# 附录 Appendix

# A 默认的驱动源映射

These are the driver default source mappings. For drivers other than bibtex and ris, they are highly experimental and subject to change (because the driver datatype itself is unstable or not well suited to bibliographic data).

#### A.1 bibtex

The bibtex driver is of course the most comprehensive and mature of the Biblatex/Biber supported data formats. These source mapping defaults are how the aliases from sections § 2.1.2 and § 2.2.5 are implemented.

```
\DeclareDriverSourcemap[datatype=bibtex] {
    \map{
     \step[typesource=conference, typetarget=inproceedings]
     \step[typesource=electronic, typetarget=online]
     \step[typesource=www, typetarget=online]
}
\map{
    \step[typesource=mastersthesis, typetarget=thesis, final]
```

```
\step[fieldset=type,
                                     fieldvalue=mathesis]
  }
  \map{
    \step[typesource=phdthesis, typetarget=thesis, final]
                                fieldvalue=phdthesis]
    \step[fieldset=type,
  }
  \map{
    \step[typesource=techreport, typetarget=report, final]
    \step[fieldset=type,
                                 fieldvalue=techreport]
  }
  \map{
    \step[fieldsource=address,
                                      fieldtarget=location]
    \step[fieldsource=school,
                                      fieldtarget=institution]
    \step[fieldsource=annote,
                                      fieldtarget=annotation]
    \step[fieldsource=archiveprefix, fieldtarget=eprinttype]
    \step[fieldsource=journal,
                                      fieldtarget=journaltitle]
    \step[fieldsource=primaryclass, fieldtarget=eprintclass]
    \step[fieldsource=key,
                                      fieldtarget=sortkey]
    \step[fieldsource=pdf,
                                      fieldtarget=file]
  }
}
```

#### A.2 endnotexml

The endnotexml driver for Biber uses the following mappings. This format is quite messy and not well suited to robust typesetting of bibliographic data. It is presented largely as an example of Biber's modular datasource abilities and also of how to map foreign data models into the Biblatex data model. Mappings from such messy and relatively simple data models are inevitably fragile and are of limited use.

```
\DeclareDriverSourcemap[datatype=endnotexml] {
  \map{
    \step[typesource={Aggregated Database},
                                                  typetarget=misc]
    \step[typesource={Ancient Text},
                                                  typetarget=misc]
    \step[typesource=Artwork,
                                                  typetarget=artwork]
    \step[typesource={Audiovisual Material},
                                                  typetarget=misc]
    \step[typesource=Bill,
                                                  typetarget=jurisdiction]
    \step[typesource=Blog,
                                                  typetarget=online]
    \step[typesource=Book,
                                                  typetarget=book]
    \step[typesource={Book Section},
                                                  typetarget=inbook]
                                                  typetarget=jurisdiction]
    \step[typesource=Case,
    \step[typesource=Catalog,
                                                  typetarget=misc]
    \step[typesource={Chart or Table},
                                                  typetarget=misc]
```

```
\step[typesource={Classical Work},
                                                typetarget=misc]
  \step[typesource={Computer Program},
                                                typetarget=software]
  \step[typesource={Conference Paper},
                                                typetarget=inproceedings]
  \step[typesource={Conference Proceedings},
                                                typetarget=proceedings]
  \step[typesource=Dictionary,
                                                typetarget=inreference]
  \step[typesource={Edited Book},
                                                typetarget=collection]
  \step[typesource={Electronic Article},
                                                typetarget=article]
  \step[typesource={Electronic Book},
                                                typetarget=book]
  \step[typesource={Encyclopedia},
                                                typetarget=reference]
  \step[typesource=Equation,
                                                typetarget=misc]
  \step[typesource=Figure,
                                                typetarget=misc]
  \step[typesource={Film or Broadcast},
                                                typetarget=movie]
  \step[typesource={Government Document},
                                                typetarget=report]
  \step[typesource=Grant,
                                                typetarget=misc]
  \step[typesource=Hearing,
                                                typetarget=jurisdiction]
  \step[typesource={Journal Article},
                                                typetarget=article]
  \step[typesource={Legal Rule or Regulation}, typetarget=legislation]
  \step[typesource={Magazine Article},
                                                typetarget=article]
  \step[typesource=Manuscript,
                                                typetarget=unpublished]
  \step[typesource=Map,
                                                typetarget=misc]
  \step[typesource={Newspaper Article},
                                                typetarget=article]
  \step[typesource={Online Database},
                                                typetarget=online]
  \step[typesource={Online Multimedia},
                                                typetarget=online]
  \step[typesource=Pamphlet,
                                                typetarget=booklet]
  \step[typesource=Patent,
                                                typetarget=patent]
  \step[typesource={Personal Communication},

#### A.3 ris

}

The ris driver reflects the fact that ris itself is a very simple and stable format. It is in fact so simple, it's hardly of any use for most Biblatex users. Again, here more as a proof of concept example.

```
\DeclareDriverSourcemap[datatype=ris]{

#### A.4 zoterordfxml

The zoterordfxml driver reads the Zotero<sup>47</sup> XML representation of its RDF format. From the Biblatex point of view, it suffers from a lack of the notion of a citation key and so is of limited use. The format may include a citation key in the future at which point the Biber driver and these default mappings will be updated. As with endnotexml, the format is somewhat messy with, in particular, a very limited way of dealing with related entries which makes the driver setup rather ugly. As can be seen below, it is possible to map into a field prefixed with "BIBERCUSTOM" which is not a real field in the data model but can be detected in the Biber driver itself and used to process a source field which does not map naturally to any Biblatex data model field as it needs special treatment. This is messy but is due largely due to messy source data models.

```
\DeclareDriverSourcemap[datatype=zoterordfxml]{
  \map{

# C 默认的排序方式

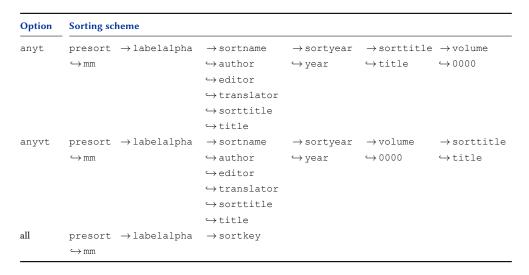

### C.1 Alphabetic Schemes 1

The following table shows the standard alphabetic sorting schemes defined by default. Please refer to  $\S$  3.5 for explanation.

Option	Sorting so	cheme			
nty	presort	$\rightarrow$ sortname	$\rightarrow$ sorttitle	$\rightarrow$ sortyear	$\rightarrow$ volume
	$\hookrightarrow mm$	$\hookrightarrow$ author	$\hookrightarrow$ title	$\hookrightarrow$ year	↔ 0000
		$\hookrightarrow$ editor			
		$\hookrightarrow$ translator			
		$\hookrightarrow$ sorttitle			
		$\hookrightarrow$ title			
nyt	presort	$\rightarrow \texttt{sortname}$	$\rightarrow$ sortyear	$\rightarrow$ sorttitle	$\rightarrow \texttt{volume}$
	$\hookrightarrow mm$	$\hookrightarrow$ author	$\hookrightarrow$ year	$\hookrightarrow$ title	
		$\hookrightarrow$ editor			
		$\hookrightarrow$ translator			
		$\hookrightarrow$ sorttitle			
		$\hookrightarrow$ title			
nyvt	presort	$\rightarrow \texttt{sortname}$	$\rightarrow$ sortyear	$\to \mathtt{volume}$	$\rightarrow$ sorttitle
	$\hookrightarrow mm$	$\hookrightarrow$ author	$\hookrightarrow$ year	$\hookrightarrow$ 0000	$\hookrightarrow$ title
		$\hookrightarrow$ editor			
		$\hookrightarrow \texttt{translator}$			
		$\hookrightarrow$ sorttitle			
		$\hookrightarrow$ title			
all	presort	$\rightarrow$ sortkey			
	$\hookrightarrow$ mm				

#### C.2 Alphabetic Schemes 2

The following table shows the alphabetic sorting schemes for alphabetic styles defined by default. Please refer to § 3.5 for explanation.

#### **C.3 Chronological Schemes**

The following table shows the chronological sorting schemes defined by default. Please refer to § 3.5 for explanation.

Option	Sorting so	heme		
ynt	presort	$\rightarrow$ sortyear	$\rightarrow$ sortname	$\rightarrow$ sorttitle
	$\hookrightarrow mm$	$\hookrightarrow$ year	$\hookrightarrow$ author	<pre>← title</pre>
		→ 9999	$\hookrightarrow$ editor	
			$\hookrightarrow$ translator	
			$\hookrightarrow$ sorttitle	
			$\hookrightarrow$ title	
ydnt	presort	ightarrow sortyear (desc.)	$\rightarrow$ sortname	$\rightarrow$ sorttitle
	$\hookrightarrow mm$	$\hookrightarrow$ year (desc.)	$\hookrightarrow$ author	<pre>← title</pre>
		→ 9999	$\hookrightarrow$ editor	
			$\hookrightarrow$ translator	
			$\hookrightarrow$ sorttitle	
			$\hookrightarrow$ title	
all	presort	$\rightarrow$ sortkey		
	$\hookrightarrow mm$			

## D 选项集合

## E 更新历史

This revision history is a list of changes relevant to users of this package. Changes of a more technical nature which do not affect the user interface or the behavior of the package are not included in the list. If an entry in the revision history states that a feature has been *improved* or *extended*, this indicates a modification which either does not affect the syntax and behavior of the package or is syntactically backwards compatible (such as the addition of an optional argument to an existing command). Entries stating that a feature has been *modified*, *renamed*, or *removed* demand attention. They indicate a modification which may require changes to existing styles or documents in some, hopefully rare, cases. The numbers on the right indicate the relevant section of this manual.

#### 3.0 2015-04-20

Improved Danish (Jonas Nyrup) and Spanish (ludenticus) translations

labelname and labeltitle are now resolved by Biblatex instead of Biber for more flexibility and future extensibility

4.5.2	
New \pernottype negated per-type sourcemap verb 4.5.2	
New range calculation command \frangelen 4.6.4	
New bibliography context functionality	
Name lists in the data model now automatically create internals for \ifuse <name> tests and booleans 3.1.3.1 and 4.6.2</name>	
2.9a 2014-06-25	
resetnumbers now allows passing a number to reset to 3.6.2	
2.9 2014-02-25	
Generalised shorthands facility	Biber only
Sorting locales can now be defined as part of a sorting scheme 4.5.5	Biber only
Added sortinithash	Biber only
Added Slovene localisation (Tea Tušar and Bogdan Filipič)	
Added \mkbibitalic4.10.4	
Recommend begentry and finentry bibliography macros 4.2.3	
2.8a 2013-11-25	
Split option language=auto into language=autocite and language=autobib	Biber only
2.8 2013-10-21	
New langidopts	Biber only
hyphenation field renamed to langid 2.2.3	
polyglossia support	
Renamed babel option to autolang 3.1.2.1	
Corrected Dutch localisation	
Added datelabel=year option	
Added datelabelsource field 4.2.4.1	
2.7a 2013-07-14	
Bugfix - respect maxnames and uniquelist in \finalandsemicolon	
Corrected French localisation	
2.7 2013-07-07	
Added field eventtitleaddon to default datamodel and styles 2.2.2	
Added \ifentryinbib, \iffirstcitekey and \iflastcitekey . 4.6.2	

multipostnote special fields	
Added \UseBibitemHook, \AtEveryMultiCite, \AtNextMultiCite,	
\UseEveryCiteHook, \UseEveryCitekeyHook,	
\UseEveryMultiCiteHook, \UseNextCiteHook,	
\UseNextCitekeyHook,\UseNextMultiCiteHook,	
\DeferNextCitekeyHook 4.10.6	
Fixed \textcite and related commands in the numeric and verbose styles 3.7.2	
Added multicite variants of \volcite and related commands 3.7.6	
Added \finalandsemicolon	
Added citation delimiter \textcitedelim for \textcite and related commands	
to styles	
Updated Russian localization (Oleg Domanov)	
Fixed Brazilian and Finnish localization	
2.6 2013-04-30	
Added \printunit 4.7.1	
Added field clonesourcekey	Biber only
New options for \DeclareLabelalphaTemplate 4.5.4	Biber only
Added \DeclareLabeldate and retired \DeclareLabelyear 4.5.9	Biber only
Added nodate localization string	
Added \rangelen	
Added starred variants of \citeauthor and \Citeauthor 3.7.5	
Restored original url format. Added urlfrom localization key 4.9.2.15	
Added \AtNextBibliography	
Fixed related entry processing to allow nested and cyclic related entries	
Added Croatian localization (Ivo Pletikosić)	
Added Polish localization (Anastasia Kandulina, Yuriy Chernyshov)	
Fixed Catalan localization	
Added smart "of" for titles to Catalan and French localization	
Misc bug fixes	
2.5 2013-01-10	
Made url work as a localization string, defaulting to previously hard-coded value 'URL'.	
Changed some Biber option names to cohere with Biber 1.5.	
New sourcemap step for conditionally removing entire entries 4.5.2	Biber only

### Updated Catalan localization (Sebastià Vila-Marta)

2.4 2012-11-28	
Added relatedoptions field	Biber only
Added \DeclareStyleSourcemap 4.5.2	Biber only
	Biber only
Documented \DeclareFieldInputHandler, \DeclareListInputHandler and \DeclareNameInputHandler.	
Added Czech localization (Michal Hoftich)	
Updated Catalan localization (Sebastià Vila-Marta)	
2.3 2012-11-01	
Better detection of situations which require a Biber or LaTeX re-run	
New append mode for \DeclareSourcemap so that fields can be combined4.5.2	Biber only
Extended auxiliary indexing macros	
Added support for plural localization strings with relatedtype 4.5.1	Biber only
Added \csfield and \usefield	
Added starred variant of \usebibmacro 4.6.4	
$Added \ \verb \  if bibmacroundef , \verb \  if field format undef ,$	
\ifflistformatundef and \iffnameformatundef 4.6.4	
Added Catalan localization (Sebastià Vila-Marta)	
Misc bug fixes	
2.2 2012-08-17	
Misc bug fixes	
Added \revsdnamepunct	
Added \ifterseinits	
2.1 2012-08-01	
Misc bug fixes	
Updated Norwegian localization (Håkon Malmedal)	
Increased data model auto-loading possibilities	Biber only
2.0 2012-07-01	
Misc bug fixes	
Generalised singletitle test a little	Biber only

Added new special field extratitleyear ..... 4.2.4

Biber only

Customisable data model	Biber only
Added \DeclareDefaultSourcemap4.5.2	Biber only
Added labeltitle option	Biber only
Added new special field extratitle	Biber only
Made special field labeltitle customisable	Biber only
Removed field reprinttitle	Biber only
Added related entry feature	Biber only
Added \DeclareNoinit	Biber only
Added \DeclareNosort	Biber only
Added sorting option for \printbibliography and \printshorthands	
3.6.2	Biber only
Added ids field for citekey aliasing	Biber only
Added sortfirstinits option	Biber only
Added data stream modification feature	Biber only
Added customisable labels feature	Biber only
Added \citeyear* and \citedate* 3.7.5
